EX CATHEDRA.

Stand Development. An article by W. Heinicke in "Photographische Mitteilungen" suggests to us that the advantages of "stand development" have been rather over-rated by German photographers. They have recommended it almost indiscriminately, if we except the case of plates which have been decidedly under-exposed. In this country stand development has not found much favour. We ourselves have met with certain disadvantages in its use, which would make us hesitate to adopt it for a series of negatives to which we attached importance. Not only have we found the objectionable halo dividing a strong high-light from a deep shadow, but have also met with markings of a very peculiar character upon plates developed in this way. These markings partake of the nature of irregular lines, on one side of which the density differs from the other side. They may be due, perhaps, to defects in the plates, but we are inclined to think a fall in temperature at the surface of the solution may initiate them. It is remarkable that these defects do not appear in plates from the same batch developed in the ordinary way. From this we infer that the slow reduction of the silver bromide by an alternated developer is attended by risks which the quicker methods of development are free from. The recommendation of W. Heinicke, however, to use stand development for a series of negatives of definite correct exposure is not without advantage.

He suggests that one plate should be developed first with a solution of definite strength, and the time ascertained for producing a negative of the desired strength of gradation. If the other plates of the series are then developed for the same length of time under similar conditions, a series of negatives resembling each other throughout will be obtainable. The writer of the article to which we have referred concedes that it is impossible to eliminate the effects of widely different exposures by means of stand development, and in this we agree with him.

Photographic Goods for Tropical Countries. An interesting letter, published in "Photographische Industrie," draws the attention of manufacturers of photographic materials in Germany to the precautions which must be observed in exporting goods to Java. After drawing attention to the fact that Dutch is the dominant language, and that German is more generally understood than English, the necessity for observing the decimal system of measures and weights is emphasised. This also implies the use of the standard Continental sizes for cameras and plates. We give prominence to this more particularly because we have recently seen a similar recommendation regarding apparatus and material exported to Roumania. After the frequent warnings which have been given, we doubt, however, if English manufacturers persist in disregarding such essentials for supplying countries using the decimal system. If they send English sizes, it must be rather with a view to supplying the ubiquitous British traveller. For Java, like other tropical countries, all apparatus and material should be of the finest quality. The wood should be well seasoned. The use of iron should be avoided, if possible, but if otherwise the parts should be plated. The high character of English cameras of best make and the excellent quality of English plates, combined with their stability under adverse conditions, should give our manufacturers the leading position in countries like Java.

* * *

An Improved Glass. It is generally recognised that many kinds of glass are easily attacked by chemical solutions. Some kinds of optical glass will not even resist atmospheric influences. The analytical chemist frequently has to take the instability of glass into account as affecting the results he obtains. For some years past quartz has received attention in the manufacture of glass, and we now read in "Photographische Kunst" that Dr. Heraeus, of Hanau, is using rock crystal for the manufacture on a commercial scale of small flasks and other vessels for chemical purposes. Rock crystal becomes plastic at a temperature of 1,350 deg. C. and at 1,700 deg. C. it

melts. The cost of manufacture is necessarily high, and a small crucible of the size of a wine-glass costs from 15s. to 20s. The work is very fatiguing for the glass-blower, and he cannot remain at it longer than five hours a day. The advantage of these vessels is that they are uninfluenced by any solutions save alkalies and phosphoric acid. They are also very little affected by differences of temperature on account of their low co-efficient of expansion. The crucibles may be made white hot, and then plunged into cold water without risk of breaking. At present the manufacture is confined to small utensils, such as flasks, retorts, tubes, and crucibles.

* * *

Platinum If report is to be believed, there is some prospect of this metal becoming much cheaper, not because any new source of it has recently been found, but because the demand is likely soon to receive a check. Many of us can remember when platinum was about one-fifth of the price it now fetches, and at that time its principal use was for certain laboratory utensils. Platinum dishes of considerable size were used by chemists who had to deal at times with considerable quantities of concentrated acids, for it was the only available metal which would resist their action. And when the price of it suddenly went up with a bound, the hearts of many must have rejoiced in the knowledge that their platinum vessels had become almost as valuable as vessels of pure gold. This sudden rise was due to the demands made by the electricians, platinum being the only metal with the same co-efficient of expansion as that of glass, platinum wires being requisite for sealing into the little glow lamps to make connection with the carbon filament within. And the number of glow lamps now in use in this country alone must be reckoned by millions. It is now reported that a French company is about to exploit a new metallic alloy, which is found to effectually replace platinum for the wires of these electric lamps, while its cost as a raw material is infinitesimal in comparison. The platinum adheres to the glass as if cemented to it, and no metal has yet been found that would behave in exactly the same way. Nor will this new alloy. But used in conjunction with it is a special cement which makes quite as tight a joint, and which is not affected by heat or moisture. If the price of platinum comes down, as it seems bound to do if these anticipations are well founded, photographers will benefit more than others.

* * *

Old types of Lenses. A few years ago the Royal Photographic Society manifested some interest in the

preservation of specimens of old types of lenses, and we believe the nucleus of a collection exists at 66, Russell Square. The rapid disappearance of these interesting instruments prompts us to draw attention once again to the subject. We know what difficulty Dr. Moritz von Rohr has had in endeavouring to find specimens of certain types. The death of old photographers and the dispersal of their apparatus make it increasingly difficult as years pass by to form a complete collection. Unless a serious attempt is soon made to secure these relics, specimens of some kinds will be lost for ever. In the earlier days of photography, English opticians exhibited great fertility of resource in optical construction. Their methods, however, were largely empirical, and we have few, if any, data upon which to work, if we desired to reproduce the lenses. We should be glad to see a small committee formed by the Royal Photographic Society to take this matter in hand. The work might even be extended by providing

means for the preservation of specimens of new types as they appear. Opticians, no doubt, would be quite willing to assist in the formation of such a collection, if it were known that the specimens would be preserved as records of their work.

* * *

Railway Pictures.

No one can reasonably complain that our railway companies are not good patrons of art generally and of photography in particular. At the various stations are displayed by the different companies gorgeous cartoons in colours showing representations of the splendid steamers which they own, together with well-executed drawings of the principal places on their lines of route. All these pictures exhibit evidence of everlasting good weather and smooth seas. The skies are blue, and are flecked with clouds, or are portrayed under the warm influence of sunset effects. The plainest of plain seaside resorts, under this seductive colouring, look as if leaden clouds were unknown there, and as if bathing was a practicable luxury all the year round. As to rain, surely there is no such thing in a country where the sun, like radium, is pouring forth incessant heat. The glare of the desert of Sahara sinks into insignificance beside the wealth of genial sunshine lavished upon the glorious prospect of Felixstowe, Cromer, and Walton-on-the-Naze. It is the same with regard to the works of art which have transformed our railway carriages into picture galleries. But these last are photographs, most of them owing their origin to the Photocrom Company, and real works of art many of them are. Skilful colourists have turned these pictures into a most attractive cross betwixt a photograph proper and the chromo-lithograph; but the beholder knows all the time that the initial work is done by the camera. We feel convinced that these pictures must exert a potent influence in attracting holiday seekers to the places so invitingly depicted. "Where shall I spend my holiday?" asks many a weary toiler as he is daily dragged to town by the suburban line upon which he is a season ticket holder. And then he looks at the photographs and inwardly remarks to himself, "What a lovely place Blankton-on-Sea must be." The bluest of blue skies is spread like a canopy over the place. The cliffs are crowned with a green mantle, and many hued rocks stand out in contrast to a sea shimmering in the sunlight. There is just enough wind to carry along on the bosom of the sea one or two white-winged yachts, and crowds of children are paddling in the shallows. Here is peace, quiet, scenery—all the conditions of an ideal holiday. How different to the water-logged fields and the frowsy brickwork which border the railway on the edge of the modern Babylon! A few weeks later the weary one takes a ticket to Blankton, and arrives there on a wet day. It has been wet for weeks. Perhaps this is the reason that all the colour is washed out of it. It goes on raining and the cliffs, which looked so pretty in the picture, are dull, grey, uninteresting things without a trace of beauty about them. From the lodging house window he looks upon a troubled sea, which is also grey. Everything is grey, and he feels as if Blankton has been destined not only to sow a crop of grey hairs on his unfortunate head, but to bring them with sorrow to the grave. But the beautiful pictures have done their insidious work, and the railway company have pocketed several fares to Blankton.

* * *

The Metric System.

Every one agrees that our British system of weights and measures is most confusing and in urgent need of reform. One of the first

MISCELLANEOUS TRADES (continued)

ALL our Second-hand Goods are now being cleared out. No reasonable offer refused. We hold the choicest collection of cameras and lenses, backgrounds of any other firm in the kingdom. Everything will positively be cleared regardless of cost. Don't miss this opportunity, which may never appear again in a lifetime.—Smedley.

A CHARMING 12 x 12 Newmarket Studio Camera and Stand; new design; built for exhibition purposes; has nearly 5ft. extension, large roller slide, extra adapter repeating back, and smaller slide; walnut and nickel; absolutely the finest camera in the world. Price only £20 to clear, worth double.—Smedley's, Blackburn.

A NINE-PIECE Stonework Accessory, giving about 30 changes; absolutely the most useful accessory made; all parts can be used separately, and each part interchangeable. Price only £3 15s.—Smedley's.

A CHARMING 10 x 8 Group Background, interior or exterior, 30s.; 12 x 8 continuous, 35s.; 8 x 7, 25s.; any design painted to order. We still hold out position as the background kings.—Smedley's.

A VERY fine 1-1/2-Plate Studio or Outdoor Camera, square leather bellows, double swing back, 3 slides, 9 x 7 portrait and group lens, with Iris diaphragms, 3-fold stand; price, lot, £9 10s.; great bargain.—Smedley's.

ABOUT £5,000 worth of High-class Photo Apparatus and accessories, just about to be cleared; any reasonable offer accepted. Send for new list at once and state requirements. An opportunity in a lifetime.—Smedley's, Blackburn.

AN Exceptionally Fine 12 x 10 Complete Outdoor outfit, built to special order; every possible movement, 3 slides, R.R. lens, Iris, 3 fold patent stand, and lock-up case. Price only £12; equal new; well worth double; approval anywhere.—Smedley's.

A MARVELOUS Offer.—A 12 x 10 Latest Patent Outdoor Camera, with swing front and every other movement, 3 double slides. Price only £5; giving away price; well worth double; approval.—Smedley's.

A 7 1/2 x 5 CAMERA, by Hare; 3 double slides and leather case, accept £3 10s.; half-plate camera, slide, R.R. lens, stand, shutter, and leather case, £2 10s.; great bargain.—Smedley's.

ANOTHER Gigantic Bargain.—Whole-plate Portable Camera, finest possible quality, 3 double slides, R.R. lens, T. and L. shutter, 3-fold tripod, and lock-up case; well worth £12; price 25 17s. 6d.; greatest bargain ever known.—Smedley's.

A MARVELOUS Offer.—A first-class 12 x 10 Field Camera, latest pattern, every movement; most efficient camera ever made; complete, with double slide; price £3 17s. 6d.; approval.—Smedley's.

A MAGNIFICENT 15 x 12 Outdoor Camera, built to special order, regardless of cost, extensive rising front, 3 slides, Ross 15 x 12 Rapid symmetrical lens, 3 fold stand, and 2 lock-up cases; the whole outfit equal to new; price for a ready sale £22 10s.; wonderful bargain, worth £50.—Smedley's, Blackburn.

A WATSON'S 18 x 16 Premier Camera, complete with large slides, extra adapter repeating back, with smaller slides for 24 plates, side by side; made for exhibition—equal new; £20. Great bargain.—Smedley's, Blackburn.

ARTIST (experienced) colours photos, oil or water; also copies direct on canvas, portraits, landscapes, etc.—Frank Ramsey, Balmaln, Goodrich Road, Dulwich, London.

ARTISTIC Finishing in B. and W., Monochrome, Water Colours; best work; trade prices; prompt return; enlargements all processes.—C. A. J. Earnshaw, 97, Upper Parliament Street, Nottingham.

A WHOLE-PLATE Quick Acting Portrait Lens, by Clement and Gilmer, F. 4, rack focussing; almost new; £2 18s. 6d.; worth double.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A 7 x 5 BUSOH Portrait Lens, Iris; new condition; bargain; £2 7s. 6d.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A No. 3 DALLMEYER Berghelm Portrait Lens; new condition; whole-plate size; £5.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A GRAND 4-plate Mahogany Body Enlarger, 8 1/2 in. condenser, Russian iron lantern body, complete with carriers; new condition; £5 12s. 6d.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A WHOLE-PLATE Quick Acting Portrait Lens, by Clement and Gilmer, F. 4, rack focussing; almost new; £2 18s. 6d.; worth double.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A 22 x 18 RAPID Rectilinear Lens, by Staley, Iris F. 8; almost new; £5 7s. 6d. Cost £10. Genuine bargain.—City Sale and Exchange, 81, Aldersgate Street, E.C.

A DALLMEYER 5 D. Portrait Lens, size 12 x 10; quite new condition; £11 17s. 6d. Cost £26.—City Sale and Exchange, 81, Aldersgate Street, E.C.

ARTISTIC Printing for the Trade, Plat., Sepia Plat., and Carbon only; satisfaction guaranteed. Sample print free from any neg. for postage. Write for terms.—Proprietor, 8, Station Road, Clacton-on-Sea.

BRUCE'S Non-shifting Retouching Medium, unaffected by varnishing; splendid tooth; advertised 10 years; used by best firms and schools; 1s. post free.—4, Villas-on-Heath, Vale, Hampstead, London.

BROMIDE Post-Cards.—Good side line for Photographers, 1s. 6d. per dozen; 15s. a gross. Portraits, views, etc.—Edmeads and Co., Burchell Road, Peckham, S.E.

BLACK and White Finishing, Retouching, Colouring Photos, Enlarging; good work only; terms moderate. — Address Miss A. Ramsay, "Balmaln," Goodrich Road, East Dulwich, London.

BROMIDE Enlargements; first-class only; 8 1/2 x 6 1/2, 1s.; 10 x 8, 1s. 3d.; 12 x 10, 1s. 6d.; 15 x 12, 2s.; 18 x 15, 2s. 6d.; 20 x 16, 3s.; cash with order.—C. Faulkner, 262, Seven Sisters Rd., London. Estab. 1884.

BROMIDE Enlargements.—Best results guaranteed, nicely finished in B. and W. on P.S. mounts; 12 x 10, 3s.; 15 x 12, 4s., carriage paid.—Melville Morgan, 66, Market Place, Great Yarmouth.

BROMIDE Enlargements.—15 x 12, 1s. 4d.; 12 x 10, 1s., etc.; work guaranteed; finishing B. and W., copying, etc. Send for list.—Birmingham and Co., 340, Balmaln High Road, S.W.

BE Wise and Up-to-Date.—Send for our second-hand list, just out; over £5,000 worth of choicest cameras, lenses, apparatus, and accessories of every description; all being cleared regardless of cost.—Smedley's.

BOARDMAN'S Electric Light Apparatus, used in 200 studios. Send for circular or call—10, Southwark Bridge Road, London, S.E. (near the Bridge, within five minutes of Cannon Street).

CLEARING Out all our Backgrounds; over 500 to select from; here are a few choice lines: 5 by 4 cloud for head and shoulders, 7s. 6d.; 8 x 7 scenic, either interior, exterior, seascapes, conservatory, or park, 15s. each; 8 x 8 ditto, 20s. each; cash returned if not satisfied.—Smedley's.

CLEARING Out all our Stock of Mounts at enormous reductions in prices. Send for sample parcel, 6 stamps; prompt delivery, and no charge for printing on orders of 500.—Smedley's, Blackburn.

CHAS. BURTON, 45, Elmsmore Road, Forest Hill, S.E., executes first-class work in monochrome and water colours, retouching, enlarging, and designing. No third-rate work undertaken.

CLEMENT and GILMER Cabinet Portrait Lens, F. 4, rack focussing; fine order; 37s. 6d.—City Sale and Exchange, 81, Aldersgate Street, E.C.

CABINET Portrait Lens, by Durand, F. 4, rack focussing; fine order; 17s.—City Sale and Exchange, 81, Aldersgate Street, E.C.

CCHEAP and Good.—Lanterns and Slides (Collodion). Slides, coloured, sets, slipping, etc., 6s. per doz.; plain, 3s. per doz. Send stamp for list.—H. Eagle, Studio, Harbury, Warwickshire.

ENLARGEMENT 12 x 10 Canvas Stretcher, beautifully painted in Oils, gold frame, 8s. 6d. free; send neg. and print with remittance.—Chas. Hewitt, Exhibitor, 14, Windfold Road, Leeds.

BOOK NOTES

(To be continued weekly.)

Photographic Reference Books.

FEW CRAFTS of the same size are so fully supplied with books of reference as is photography. Apart from such handy, everyday useful books as **Figures, Facts and Formulae**, there are three or four large volumes, truly encyclopædic in their scope and authoritative in their accuracy.

A **Dictionary of Photography** by E. J. Wall, originally published at 2/6 in 1889, has grown through successive editions, and latterly has been extended and edited by T. Bolas, F.I.C., F.C.S. until its present, eighth edition runs to 656 large pages and is a very cheap reference book at 7/6 nett; post free 7/10 (abroad 7/11).

The **Encyclopædia of Photography** by Walter E. Woodbury, is an extensive and catholic compilation, consisting of some 755 pages, at the same price (7/6 nett; post free 8/-).

Wilson's Cyclopædic Photography, the greatest work of one who was the most influential editor in the whole photographic world, is very wide in its range; deals with the earlier as well as the more modern processes; and gives especial attention to the practical and professional sides of photography. The death of Dr. Wilson in June last, renders it extremely unlikely that any further edition of "**Cyclopædic Photography**" will be issued, so that everyone who wishes to have a real working library should secure a copy of the current edition.

Handsome cloth: 453 pages, with some 247 illustrations, Price, 7/6 nett; post free 8/-. Of all Photographic Dealers, Booksellers, &c., or

HEREFORD.

troubles of boyhood is found in the effort to understand the intricacies involved in the differences between troy weight and avoirdupois weight, and in the assimilation of perches, rods or poles, and all the rest of it. The time taken up in mastering this jargon—and we believe that it is very seldom mastered—might be far more usefully employed in other branches of education. The photographer who has to deal sometimes with an ounce which contains 480 grains, and at other times with one which has only 437½, is only one out of a large number of workers who are perplexed with the chaotic condition into which our methods of measuring have sunk. Our French neighbours more than a hundred years ago made a clean sweep of their own weights and measures, and formulated a most excellent system which has since been adopted by nearly every country in Europe except our own. And by comparison with this metric system, as it is called, our own happy-go-lucky methods are worse than ever. More than this, they represent a distinct loss to our traders, whose price-lists are often thrown aside by Continental buyers for the sole reason that they are not understood. A serious effort is now to be made to make the metric system compulsory in Britain, and it is said that our Colonies are anxious and ready to make the reform directly it has been accomplished at home. A bill is to be introduced early next Session in the House of Lords to forward this end, the first reading to be moved by Lord Belhaven, and seconded by Lord Kelvin. The Upper House is chosen for its introduction because it is thought that the Commons will have their hands pretty full with the Fiscal Question. But it is hoped that sufficient pressure will be put upon the Government to make it their own Bill in the House of Commons. So far as photographers and photographic dealers are concerned in this question, it will be but a slight effort to them to substitute the gramme for the grain. Many works on photography already attach both the English and metric weights to their formulæ, and all laboratory workers use the latter in preference to the former. In certain businesses the introduction of the metric system may lead to much initial expense; but the photographers' wants in the way of measuring vessels and weights are so modest that a few shillings will do all that is needful. We wish all success to the proposed change.

* * *

Surgical Possibilities. We think that we can see a new opening for the pushful photographer in the possibilities which arise from the recent ear-grafting case in New York. Put briefly, the history of the case was this: A rich man lost his ear, how it is not stated, nor does it matter. Perhaps some one boxed it—at any rate it was boxed and buried. He offered the sum of £1,000 to the man who would give him a new ear—or, to be strictly correct, a second-hand ear. The man was found, and also the surgeon who undertook to perform the operation. And so the ear was transferred from one head to the other. The surgeon is naturally elated at his success, and has expressed his belief that if the same system be followed which he adopted in the grafting of this ear, there should be no difficulty in grafting other members such as hands and feet, and possibly legs and arms. If this be the case, of course, the thing will be placed on a systematic basis, and there will be an "exchange"—just like a telephone exchange, when the business can be effected. Any one with a superfluous nose, or other member, will be able at once to turn it into hard cash. On the other hand, anyone minus that, or any other distinctive feature will be able to obtain what he wants according to a fixed tariff.

Of course, a register of plus and minus members will be a necessity, and that register, to be of real use, must be illustrated. It is here that photography will come in. No one would think of buying a nose unless he had some idea as to its size and shape, and in this delicate matter mere verbal description would be of little or no use to him. But if he could see an actual photograph of the member, life-size, while at the same time he received a written guarantee of its performance as a sniffer, he would be comparatively safe. If we could obtain a list of unfortunates whom war and accidents by flood and field have deprived of their birthright in the matter of legs, arms, and minor members, we should see how wide a field of operation there is for such an institution as we suggest. It may be thought that the number of persons who are willing to part with anatomical details must be very limited. But this is not so. We are told on good authority that at many of the Continental hospitals there are crowds of men always in waiting who are willing to be experimented upon by the surgeons for a consideration. Many of these would consent to part with a limb or two if paid properly for the sacrifice. As to the ethics of the business, there would be no difficulty. If they were rats, or guinea-pigs, or frogs, there would go up a howl of indignation, but as they are mere human beings it does not matter.

* * *

More Radium.

"Familiar in our mouths" is fast becoming this word radium, and it seems to be permeating every stratum of human society. Only the other day we were accosted by an aristocratic beggar in Oxford-street, who said, "Excuse me, but can you oblige me with a penny to purchase a morsel of radium." Of course, the poor fellow meant bread, but he had been reading about radium, and his tongue played him false. There are two out of many good reasons why people should have allowed the new element to take such a hold upon them. Firstly, it is the most costly thing ever known, and we are all worshippers of mammon; and, secondly, it is the nearest approach to the philosopher's stone which has yet been discovered. Being worshippers of mammon, that stone, which would have the property of turning copper into gold, would be a most convenient acquisition. But the wonders of radium as recorded in the British newspapers and magazines pale into insignificance when we read some of the marvels recorded of it by trans-Atlantic journalists. Some of these yarns are possibly true, but we have a notion that others of them are due to the exuberant imagination of the perspicuous scribe. One of these gentlemen tells of certain experiments which have been made with radium at the Pasteur Institute in Paris, from which it would seem that even a few milligrams of it will exercise a baleful effect upon animal life. A bag containing five centigrammes of radium chloride was suspended over a cage of eight white mice, father and mother and six little ones, for three days. Nothing happened then, but some time after the radium was removed the mice lost all their hair, except that on their heads; they then became blind, and subsequently they all died. Rabbits and guinea-pigs also died when the fatal bag of radium was placed near them, and even the unhatched chicken in the egg was cut off in embryonic youth. But this is as nothing to what happened when certain larvae, which live on flour, were submitted to the action of the rays. The little worms were placed in a flask exposed to the rays, whilst another family was placed in a similar flask not so exposed, each having a little flour with which to sustain itself. After some weeks it was found that several of the radium-exposed worms had gone to a better world, but

some which had hidden in corners, away from the direct action of the radiations, had survived; but they had "got no forader." They were still larvæ, while the untreated family in the other flask had long ago turned into moths and hatched their eggs into other larvæ. It was as if the growth of a man had been arrested at the age of twenty, while his brothers and sisters went on living for two hundred years or more. This remarkable result opens up wondrous possibilities for experiments upon the domestic baby when radium becomes cheaper. But this is not all. Tadpoles, exposed to the rays for four days, were turned into monsters, which took on "a new form, with an increasing atrophy of the tail, and a curious wrinkling of the tissues at the back of the head; in fact, they may be said to develop a new breathing apparatus, quite different from that of ordinary tadpoles." It is confidently asserted that by the help of radium it will be possible "to produce new species of moths, butterflies, perhaps birds and fishes, by simply treating the eggs with radium rays, the result being that interesting changes will be affected in the colouring and adornment." All this is very interesting, but it must be remembered that the fortunate holder of stock in radium can say what he likes about it without fear of contradiction. Scoffers are powerless if they have no radium with which to parry the conclusions arrived at by their opponent. Unfortunately there seems to be no probability of radium being cheaper, unless some other source of it than pitchblende is discovered. Perhaps now that the "Times" has finished with its "Encyclopædia Britannica" spec—for which relief much thanks—it may see its way to offer prizes for a cheaper source of radium. Until that discovery is made, we must all be at the mercy of the fortunate few who possess any

PHOTOGRAPHIC ADVERTISING.

THE last few years have worked a wonderful change in the methods adopted by traders who advertise their wares in popular magazines or other periodicals. What has long been known as the "displayed" advertisement, consisting of large, small, and grotesque type cunningly interwoven, no longer holds the premier position. The advertisement must be so associated with a pictorial embellishment that it will immediately attract the eye of the casual reader. Skilfully-arranged lettering is no longer sufficient for the purpose, there must be a picture, and the picture must command attention either by its subject, its artistic excellence, or by its comicality. But the comical advertisement is hardly to be commended, for however good it may be, it palls upon one by frequent repetition, and when insisted upon week after week and month after month, it has a positively irritating effect upon the nerves, which is apt to prejudice many people against the article advertised. In fact, it becomes a chestnut, and we all resent chestnuts as stale and flat.

As we glanced lately through the advertisement pages of a popular American magazine we could not help admiring the pitch of perfection to which these trade advertisements are carried by our transatlantic cousins. Nor could we help remarking how largely photography is employed in the work. Some of the advertisements, too, although not actual photographs, are reproduced by the half-tone process from wash-drawings of such artistic excellence that they would not be out of place in the inner pages of any high-class publication.

As examples of these last, let us refer to the advertisements of one or two firms of tailors. We all know what the

usual clothiers' advertisement is like; a row of wooden figures, very like the terrible tailors' dummies which we see in East-end shop windows: lifeless dolls, with clothes fitted upon them without a single crease. But in these pages we find a very different kind of picture. Here is one which is intended to set forth the merits of a certain make of overcoat, and very well does it do so. We see a group of men standing, apparently on the slope of a grand stand at some racecourse, all eagerly watching the progress of something in front of them. The figures are easy and natural in pose, and they look like gentlemen. As a picture we might find fault with the circumstance that each man is arranged in an overcoat of much the same pattern, but of course this is the very object of the composition. We feel convinced that anyone requiring such a garment would be much sooner induced to purchase one after seeing this picture, than he would from dwelling on the beauties of the tailors' dummy. In another advertisement, also advocating seasonable wearing apparel, two men are seen walking up a street, the attitudes being natural, and showing off their coats to perfection. At the same time one would never guess that this was a tailoring advertisement except for the context.

A boot does not seem a promising thing from a pictorial point of view, but one shown here immediately attracts the eye simply because the picture is so beautifully executed as a half-tone block, and so well printed that one can note every stitch as well as the name of the maker sewn upon the tape which projects from the interior of the boot. Here is an advertisement of a cabinet intended for the filing of documents, an elaborate piece of furniture with innumerable drawers of different shapes and sizes, some shut in and others drawn out. We can at once appreciate the construction and working of this piece of apparatus, for the picture before us is a veritable photograph, so well reproduced that the figuring of the grain of the wood is plainly apparent. Another page is devoted to an advertisement of Christmas and New Year's gifts, principally articles of jewellery. These again are photographs from the objects themselves, and we can at once see every detail of the design, while reference letters attached guide us to description and price.

Photography is also used in these advertisement pages in a slightly different way. For instance, a certain compound for cleaning kitchen utensils has for its illustration a photograph of a neat housemaid in the act of polishing up the articles which come under her care. Other advertisements are well illustrated in much the same effective manner.

These photographic advertisements not only form an interesting study to those, who like ourselves are critical in such matters, but they really add to the general interest of the publication in which they appear. This is a distinct gain not only to the proprietors of the magazine but also to readers, who are too apt to resent anything in the shape of an aggressive advertisement thrust upon their notice whether they will or no.

A perusal of these advertisement pages has prompted us to ask the question, "Might not photographers in this country of ours add to their incomes by undertaking to make pictures for this especial purpose?" Of course, it is done by the few, but an examination of the pages of any of our own popular magazines will soon show that the ground is not covered to any great extent. Beyond an occasional photograph of a pretty face, which generally has nothing at all to do with the announcement to which it is affixed, and is merely put in to attract attention, we see little in the way of half-tone blocks—and we are convinced that if advertisers realised the advantages which

accrue from their use, their employment would be as general as they are in the American publication to which we have adverted. The fact is that our American friends understand the art of advertising, and it is an art, much better than we do. They make a study of it, and therefore they succeed where we often fail. A ready example of their skill in this respect is supplied by the familiar word "Kodak." An English firm would never have taken the trouble to invent such a word, but would have been content to use the term "camera" to the end of time. Look at the result of this happy inspiration upon the part of one who had a genius for advertising. Kodak not only stares one in the face from the advertisement pages of every prominent journal, but it assails one on omnibuses, trams, and every other kind of public vehicle. More than this it has grafted itself upon our language, not only as a substantive, but as a verb. Kodak has in fact now such a wide application that its originators have constantly to remind people that it is not a generic term for a hand camera, but should be applied to one manufacture only.

The importance of effective advertising has so impressed itself upon the American mind that schools of advertising are now in the course of formation, and the British Consul at Chicago thought the scheme of sufficient interest and importance to report officially upon it a few months ago. He states in this report that the enormous sums spent upon advertising in all branches of trade in the United States has actually created a new profession, and that the study of advertising as a science is now being taught in special schools.

That something of the kind is urgently required on this side of the Atlantic can be quickly seen if we glance at the advertisement pages of many of our newspapers and magazines. Many advertisers seem to be under the mistaken belief that because they have a certain space to fill, they must positively crowd it with type. In order to get all the matter into the space, the compositor is forced to use small type, and people will not read small type unless it is something of overpowering interest. Instruction in a school of advertising would prevent any trader falling into this error, and he would probably content himself with a word or two in large letters, with his name and business address.

If anyone could possess himself of the money which has been spent in unremunerative advertising he would be the richest man on earth. It will be the aim of the new schools in America to stop this waste of substance and of effort by educating men into the science of advertising. Such a man ought to be able to secure a very large salary as manager to the advertising department of a railway or steamboat company, or of any large house of business. He would be able to so check the results of different systems of advertising, and the medium through which advertisements were brought before the public, that his help in any large business firm would be of incalculable value.

It is not alone the concise wording of the advertisement that has to be considered, but also its effective illustration, and this will depend as much upon the way in which the artist is instructed, as upon the artists' pencil. As we have seen, in the instances given, the illustration is the thing to catch the public eye. And there is another advantage to be considered in the launching of a good pictorial advertisement. If it takes a firm hold of public attention, jokes will be made about it, and as likely as not it will be parodied. In these ways its circulation will be increased perhaps twenty fold, without one penny more to pay by the fortunate advertiser.

But the main point of interest to our own readers will be found in the extensive use that is being made of photo-

graphy in modern advertising, a use which owing to the general employment of the half-tone process block is likely to increase rather than diminish. We feel confident that the photographer who depends for his bread and butter solely upon portraiture, and is often perplexed to solve the problem of making two ends meet, would gain by giving serious thought to this system of advertising. If he can show people that he is able to draw up an effective advertisement and illustrate it in a taking manner he will soon find customers ready to patronise him. It is only reasonable to suggest that when a new application of photography is started photographers should benefit by it. Those who care to take the hint which we have given in this article will be better able than their fellows to laugh at the free portrait and enlargement swindles which are now so rampant in our midst.

STALE DRY PLATES.

I.

Most photographers have experienced the disadvantages of working with plates that have become more or less stale, and with the ultra-rapid isochromatic plates and films that are now being generally used, the proportions of negatives spoilt, or, at least, marred by the use of stale emulsions is considerably greater than was the case a few years ago, although the skill and care exercised by the manufacturers have brought dry-plates to a really marvellous degree of efficiency.

In the larger towns where plates can be obtained from reliable dealers whose sales are large enough to enable them to keep a supply of fresh plates always on hand, the evil of stale emulsions is not experienced to any appreciable extent, but in small towns and villages where the demand for plates and films is limited, the local dealer's stock of plates is often considerably the worse for keeping. One of the chief difficulties a small dealer has to contend with, is the number of brands of plates that are at present on the market, and as each amateur has his own ideas regarding the best kind of plate, the local dealer has to stock the wares of at least a dozen different makers. This aggravates the stale-plate difficulty considerably, as the dealer does not get a fair chance of disposing of his plates while still fresh. The writer has recently been experimenting with numerous brands of plates in the various stages of deterioration caused by stale emulsion. The experiments for determining the effects of staleness were conducted on a batch of several hundred plates of various sorts and sizes, and were already showing symptoms of staleness when purchased by the writer four years ago, and which consequently gave typical but exaggerated evidence of the effects produced by age on gelatine emulsions. If a very stale plate is examined in daylight before development it will be noticed that the edges of the plate are darker than the central portion, and are generally slightly iridescent in appearance. The depth and intensity of this outer band increases with the age of the plate.

All stale plates, however, even when obtained from the same maker, do not present the same appearance before development. In the case of a particularly stale box of plates examined by the writer, the emulsion had changed to a light brown colour without iridescence; this change of colour was visible from the edges almost to the centre of the plate. Another box of the same brand showed strongly iridescent edges of a quarter of an inch in width, the remainder of the plate being practically unaffected.

The foregoing remarks do not apply to orthochromatic plates, as the deterioration in isochromatic emulsion proceeds equally over all parts of the plate, and is not confined to the edges. In this case the staleness is caused by the effects on the emul-

sion, of the dye used in orthochromatising the plate, and is of an altogether different character to that which is now being considered.

Most photographers will have noticed that as a rule the keeping qualities of a plate decrease as the rapidity of the emulsion is increased.

The kind of plates known as process or photo-mechanical, which are much slower than ordinary plates, keep almost indefinitely when stored in a fairly dry place. Next in order come the "ordinary" plates, which will usually produce good negatives several years after manufacture. The most rapid emulsions become stale much sooner than the slower kinds, and last of all come the isochromatic plates, the keeping properties of which are, of course, handicapped by the presence of the isochromatising agent. The writer's experience has shown that an orthochromatic plate begins to deteriorate in a year or even less; a rapid unorthochromatic plate will keep in good

FIG. 1.

Stale undeveloped plate fixed in hypo.

condition for about a year and a half, and an ordinary plate will generally last two or three years without showing signs of fog or flat images. It must be remembered that in the case of orthochromatic emulsions the whole film deteriorates; in the unorthochromatised film only the edges will show evidences of staleness.

The foregoing remarks do not apply to emulsions coated on a film instead of a glass support, as the keeping properties of films are considerably below dry-plate standard.

The effects of staleness on the film of an undeveloped dry-plate, which had been fixed in hypo, is shown in Fig. 1, the edges of which show very plainly the results of age. In this plate the stale edges of the plate resemble a lantern-mask, and the distinction between the stale portions and the rest of the film is very sharply defined. In this box of plates the silver was actually reduced, and, after fixing, the undeveloped plate showed the silver deposit very plainly under the microscope. As a rule, the silver in a stale plate is almost entirely removed by hypo, if the plate is fixed before development. In Fig. 2 the effects of the stale emulsion have given a different result. Instead of affecting only the margins, as in Fig. 1, the plate had a slightly brown tint that extended from the edges of the plate to the

middle, the centre of the film being, of course, less marked than the edges. The illustration shows the appearance of the unexposed plate after being developed for four minutes in pyro soda and fixed. Although no light had reached the film a very considerable quantity of silver was reduced by the developer. A plate from the same box was fixed before development, and all traces of silver disappeared.

FIG. 2.

Stale unexposed plate developed and fixed.

All unexposed stale plates that were tested by development showed granules of silver in the film when the plate was examined by a high-power objective, though in most cases there was not a sufficient quantity of silver to affect the printing value of the negative except at the extreme edges. Figs. 3 and 4 are reproductions of photo-micrographs, showing the appearance of an exceptionally stale plate (probably manufactured about ten years ago). These photographs show the

FIG. 3.

$\frac{1}{8}$ obj.

Photo-micrograph of silver granules from the edge of a stale, unexposed plate, developed and fixed.

relative proportion of silver reduced by development in the edges and centre of the plate. The edges of the plate show a very large number of reduced silver granules, but the deposit in the centre is much less pronounced.

A curious feature of the effect of staleness on the silver in the emulsion is that the silver can generally be removed by

hypo, if the plate has not been developed, though to all appearance the film has a considerable quantity of reduced silver at the edges when examined before fixing. As previously mentioned, however, the undeveloped plate will not always give up all its silver when placed in hypo; but, as in Fig. 1, the edges may show a strong deposit after fixation.

From the appearance of the different portions of the plate, when examined under the microscope, it would seem as if a negative taken on a stale plate would be thinner at the centre of the plate, and would increase in density towards the edges, as the microscope reveals a considerable diminution of silver granules from the edges to the middle of the plate. In practice this is not the case. In the stale portions of the negative the image does not develop so strongly as in the centre of the plate, and this counteracts to a considerable degree the extra deposit of silver caused by stale emulsion. Plates which have become stale will generally give very fair negatives if the exposure has been accurately timed, but both under and over-exposure are fatal to good results if the plates have been kept too long. Over-exposure produces a flat, foggy image, and under-

FIG. 4.

Photo-micrograph of silver granules from the centre of same plate.

exposure necessitates prolonged development, which the condition of the emulsion will not allow.

The chief enemy of emulsions, and the one that is the principal cause of stale films, is a damp atmosphere.

Heat without moisture seems to have little effect on plates, and the writer has kept plates stored in a cupboard near a furnace where the temperature was almost constantly at 80 deg. Fahrenheit, for two years with very little loss of freshness at the end of that period.

The greatest deterioration in emulsion takes place in hot, damp days, and the least in cold, dry weather. Amateur photographers, who only work occasionally at their hobby, should take the precaution of storing their plates or films in the driest available cupboard, and this will prolong the life of the sensitive films to a very considerable degree.

The writer had a remarkable experience of the time a plate will keep under suitable conditions. A packet of plates, which had been kept unopened for twenty-two years (dated and signed 1881) was given to him for experimental purposes. These plates were exposed and developed, and gave very passable negatives; the image was rather weak, but there was little tendency to fog, and the plates developed steadily. This box of plates had

been packed with strips of thick paper between the edges of the plates; the plates were thus kept apart from each other. It is needless to say that the plates were not coated with rapid emulsions.

In a recent issue of the Journal of the Royal Photographic Society, Léon Vidal recommends a bath of bichromate of potash for restoring stale emulsions. The plate is immersed after exposure in the camera in a one per cent. solution of pot. bichromate for three minutes, washed well for five minutes, and then developed; the bichromate exercises a retarding influence on development. J. I. Pigg, F.R.M.S., F.R.P.S.

A SUGGESTED PLAN FOR PHOTOGRAPHY IN COLOURS, WITHOUT THE USE OF COLOUR SCREENS.

In bringing forward the following suggestion for photography in natural colours, by a method which would necessitate but a single negative, a single exposure, and no colour screens, except an orthochromatic light filter for taking the photograph, I do so fully aware that the realisation of the plan may be somewhat remote, owing to technical difficulties in the construction of the apparatus. The theory of the method is, however, so simple, and the working of the process would be such a simple one, provided the apparatus were constructed, that I think it may be of interest to bring it into notice and briefly discuss its advantages and drawbacks. My plan may be looked upon as an extension of the Joly process of colour-photography. It differs from it in the following important point. In the Joly process, as is well known, a colour screen ruled with alternate red, green, and violet lines is placed in front of the negative during exposure, and, after a positive transparency has been made, this is viewed in contact with another similarly ruled colour screen. My proposal is to replace the artificial colour screen with its artificial spectra, by real spectra produced optically.

The following diagrammatic sketch of the arrangements will make this clearer:—Let A be an objective producing an image not more than 2 in. in diameter in the plane M. Let G be a grating of 300 lines per inch, situate in the plane M. The opaque interspaces of the grating to be twice the width of the clear spaces. Let B be a second objective, projecting an image of the plane M on the ground-glass screen S, with a magnification of two diameters. Let P be a narrow-angled prism, placed just in front of the grating, of such dispersive power that the spectra which it produces on the screen S of the clear lines just lie next to one another without overlapping.

Provided the image at M were white (or, in other words, only white light fell upon the grating), then the effect of the above arrangement would be to cover an area of four diameters on the screen with a series of contiguous spectra (150 per inch). To the unaided eye this surface would appear of a greyish white. In the diagram, part of the screen is shown covered with these spectra (of an exaggerated width). Now suppose for a moment that another grating of 150 lines per inch were laid over the screen, the lines being parallel to the spectra. Then each line of this grating would cover up the same portion of each successive spectrum and the whole field would appear to the eye of some uniform colour. If, for example, the lines covered up the red portion of each spectrum, then the field would appear in the complementary colour to red, viz., green. If the number of lines of the grating laid over the screen do not exactly correspond with the number of spectra, a comparatively quite long spectrum can be visually produced, because then the successive black lines do not block out exactly the same portions of spectra, but successive portions.

The production of this long composite spectrum, consisting of some hundreds of portions of the narrow spectra, is a rather striking experiment. However, this blocking out of spectra on the ground-glass screen by means of another grating has only been mentioned by way of illustrating the principle, and we can now consider the actual process proposed. If the screen is replaced by a photographic plate and a suitable orthochromatic filter, placed in front of the lens A, and a photograph be taken of, say, a blue flower on a white ground, the result would be that the image of the flower would be represented on the plate by the blue portions of the spectra only, and on development these portions would be darkened in the negative. Now let a positive transparency be made from this negative, and let it be placed in exactly the same position as the original negative. Remove the orthochromatic filter which was used, place some source of light at the focus of the lens A, so that the grating G is illuminated with white light, and spectra are produced in the plane of the transparency. Then we should find that the dark portions of the positive just block out all portions of the image of the flower except the blue, and to the unaided eye it would appear in its natural blue colour. It can readily be seen that composite colours, however complex, would be produced just as readily; for, provided the orthochromatic filter used was a suitable one, the colours would affect the different portions of the spectra

colour, would require to be placed in an apparatus, viz., the camera itself.

The advantages are summed up in the fact that: (1) We should have the maximum of simplicity in working the process, for it would be the same as that for making ordinary transparencies, without any additional labour. (2) Without employing colour screens, the colours would be produced by a natural optical method, securing greater fidelity of result, because the colours would be analytically correct. If it should be possible at a future date to produce paper ruled or printed with imitation spectra, as fine as 150 per inch, and the paper coated with ordinary emulsion, for contact printing, then any number of colour prints could be made from the original negative, in the ordinary way, and we might expect to see the day when amateurs could produce passable photographs in natural colours as easily as they now do ordinary photographs. In conclusion, I may mention that I have only been able to make experiments so far as concerns the visual production of colours by the method described of laying a grating on the ground-glass screen. Should this article lead any one to follow up the suggestions made, it will have achieved its purpose.

JULIUS RHEINBERG.

HOW TO MAKE PARALLAX STEREOGRAMS.

[From the "Journal of the Royal Photographic Society."]

on the plate, just in proportion to the actual intensity of the separate spectrum colours of which they are composed.

A few words as to certain practical points. The grating used would require to be made with the dark interspaces perfectly opaque. The orthochromatic filter used would require to be such that a photograph of the spectrum gave a deposit on the plate equal in density throughout its entire length. It would differ, therefore, from the usual orthochromatic filter, which is made to fulfil the condition that the deposit on the plate shall correspond to Maxwell's colour curve of visual luminosity. In viewing the photograph, a finely ground glass screen or other light-diffusing medium would have to be placed in contact with the film side of the positive, as otherwise the object would only appear correct in colour when viewed from one particular point. In place of using the prism P along with the lens B, a suitably decentred lens, without any prism at all, would probably do equally well.

We can now discuss the advantages and disadvantages if the system be properly carried out. The latter appear to me to be:—(1) The photographs would, just as in the Joly process, be less bright than ordinary ones, as a surface produced by a series of narrow spectra is necessarily less bright than a surface white all over. (2) As the optical system is essentially the same as that of a telescope, the field of view would be comparatively small. (3) The photograph, in order to be viewed in

The parallax stereogram photograph consists of a single transparent image divided into lines (100 to 150 to the inch), alternate lines forming one of a stereoscopic pair of images, and the intermediate lines forming the other image, so that it has the appearance of a pair of stereoscopic images mechanically superposed. In order that each eye may see only the lines belonging to its respective view-point, the photograph is covered by a line-screen, with a definite separation from the surface of the photograph, such that lines of the photograph covered by screen-lines to one eye, are seen by parallax of vision by the other eye. The combination of the photograph and line-screen in suitable adjustment constitutes the parallax stereogram, which, when viewed from a suitable distance, directly in front, shows the objects in perfect stereoscopic relief.

The simplest method of making the parallax stereogram photograph is by means of a camera having at the front a single plano convex lens of about 3 in. in diameter, behind which are two small openings about $2\frac{1}{2}$ in. apart in a horizontal plane (Fig. 1), so that an image is formed from two view-points, corresponding to the separation of the eyes. The image thus formed may be a perfectly sharp single image of objects at some one distance from the camera, but then objects at every other camera distance will form two images laterally displaced and superposed, exactly as in two ordinary stereoscopic images mechanically superposed. It is then only necessary to cover the sensitive plate with an opaque line-screen suitably adjusted with reference to the spacing of the lines, separation of view-points, and camera extension, in order that the light coming from the two camera apertures may form separate images in juxtaposed lines. A transparency from the negative thus obtained is then covered by a line-screen with adjustment like that in the camera, and viewed from a point corresponding effect of an ordinary double stereogram in the stereoscope. to the position of the lens apertures, in order to produce the If, however, these conditions are strictly adhered to, the result will be pseudoscopic instead of stereoscopic, just as in ordinary stereoscopic photography the result is pseudoscopic before the images are cut apart and transposed. The stereoscopic effect is obtained by shifting the cover-screen laterally the width of

one screen-line, but with the result that the perspective is distorted when a moderately-large angle of view is included.

Fig. 1.

In order that the path of the rays to or from every part of the stereogram may be absolutely identical in photographing and in viewing, the image formed through each aperture in the camera should be laterally inverted, so that the two pencils of light belonging to near objects bisect before reaching the screen, and pencils from far objects after passing through it. This may be effected by placing laterally inverting prisms in front of the lens apertures, as shown, for instance, in Fig. 2,

Fig. 2

in which w represent the path of rays coming from an object more distant from the lens on one side than the screen and sensitive plate on the other. With this arrangement the objects will be seen laterally reversed, unless photographed in a mirror, but in other respects the results will be much better than without the inverting prisms.

The employment of the inverting prisms also permits of dispensing with the large lens. The fact that the prisms may be so disposed as to direct the two pencils of rays towards the axis of the camera in the same manner as the prismatic edges of a single lens, permits of the use of two separate lenses (Fig.

Fig. 3.

Fig. 4.

3), or even of "pin-hole" apertures without lenses (Fig. 4), and this method of controlling the parallax independently of the focal length of the lenses possesses certain practical advantages. Objects can be photographed so as to appear to be at the plane of the photograph, or within or beyond it, at will. When the arrangement shown in Fig. 3 is employed, it is advantageous to have pairs of lenses of various foci, in order to keep to one camera extension, and owing to the small size of the apertures, simple lenses may be used.

The most perfect screen I have used for this work is a one-hundred lines to the inch uncovered Levy single-line screen (made to order) with "hard filling," and opaque lines twice as

broad as clear spaces. A card-mat separator is used, and the sensitive plate pressed flat by a thick plate-glass at the back in the dark slide. The requisite thickness of the card-separator depends upon the camera extension, etc., and can be readily calculated.

The cover-screens for the parallax stereograms are made by contact printing on transparency plates, from a negative made by contact printing from the original Levy screen, and intensified by mercury and ammonia. The lines should be quite opaque, and the spaces perfectly clear, and, while good enough for this purpose, such screens are not good enough for use in making the negatives.

Owing to the fact that neither the transparencies nor the cover-screens are ordinarily flat, it is necessary, in mounting them up together, to use a third glass, convex side (preferably ground, against the back of the transparency, and to exert sufficient pressure in the binding to make the inside faces parallel. It requires considerable skill to make these adjustments perfectly, but with practice it can be done very quickly.

Other means for making parallax stereogram negatives suggest themselves, but the other methods described possess certain advantages, and are, perhaps, the most interesting.

F. E. IVES.

Mr. J. W. Swan said he should like to congratulate Mr. Ives on another very ingenious contribution—one of many—to photographic progress. Mr. Ives' name came to the speaker's mind when the first paper was read the ground traversed by that paper had been so completely gone over by Mr. Ives in the past. He felt that Mr. Ives was really the true teacher of the principles laid down in that paper. They now owed to him a new debt. He had never seen anything more vivid and beautiful in stereoscopic effects than that produced by the simple and ingenious apparatus exhibited. Mr. Ives' new stereoscope had the great merit of enabling the stereoscopic image to be seen without visual effort.

After some further remarks of a congratulatory nature from those present, Mr. Swan, continuing, said that the paper and the exhibit reminded him of that by-gone time when gigantic lenses were in common use in photographic studios; when letters were appearing in the *Times*, from the pen of Sir David Brewster, severely criticising the pictorial characteristics of the photographic portraits of that period. Sir David spoke of the photographic portrait taken with large lenses as a monstrosity composed of an infinite number of superposed incoincident images, and he contended that photographic portraiture would never be natural until portraits were taken by lenses no larger than the pupil of the human eye. At that time such an increase of sensitiveness of the photographic surface as would make that practice possible was then far beyond reach, and seemed unlikely of attainment. Meeting as they did that day, and having the former state of things recalled to their memory, they might well rejoice in the progress made in the immensely-increased sensitiveness of the photographic plate which had enabled lenses to be used as small as, and even smaller, than the ideal lens of Brewster's imagination. Brewster would also have rejoiced as they rejoiced in the very general improvement in lens construction achieved during the fifty years the completion of which they commemorated that day.

[The parallax stereogram shown by the author of the paper at the Exhibition of 1902 was exhibited during the reading of the paper.]

WE regret to record the death of Mr. William Butcher, of the firm of Messrs. W. Butcher and Son, dealers in photographic apparatus, which took place on Monday week at Hastings, where he had been staying for some time.

REDUCERS.

In a recent letter on persulphate for reducing negatives some objections are made to ferricyanide on the ground of its causing stains and eating away shadow detail. These defects are not inherent in the reducer, but in the methods of using it. When negatives are free from pyro no stain is caused; but if they are taken straight from an old fixing bath contaminated with pyro, and placed in ferricyanide, stains are sure to be caused, and they seem almost incapable of being removed, although some of the stain disappears in the subsequent washing. If a negative is to be reduced with ferricyanide, it should be washed after fixing for at least five minutes, to remove hypo solution containing developer, and if pyro has been used the washing should be longer; and in all cases fresh hypo should be used for making up the reducing solution. After reduction the negative should be fixed again for half a minute in order that any undissolved ferrocyanide of silver may be cleared away. I have used the Howard-Farmer reducer for many years, and always keep some of it ready in the dark-room. My method is to put half a pound of ferricyanide into an old pyro bottle, which is filled up with water and occasionally shaken. This forms practically a saturated solution. This method may not be very scientific, but in my hands it answers very well, and I have used it for ten years and more. When a negative has to be reduced, a few crystals of hypo are put into a dish, and, if the weather is cold, some warm water is poured over them. (At this time of year I always have some warm water handy in the dark-room.) Some of the saturated solution is poured into the dish, the amount being regulated by the nature and amount of reduction desired. If the negative is too dense, and likely to produce a hard print, the reducing solution is used very strong, and the amount of hypo, at the same time, is made proportionate. The water-tap should be turned on and the dish of solution kept close to it, the negative is plunged into the reducer and rocked vigorously for three or four seconds, then snatched from the dish and held under the tap, before being examined for density. It will be found that the high-lights have been reduced in greater proportion than the shadows. The latter, as a rule, do not appear to have been affected at all, and the result is a reduction of contrast. This method is rather heroic, and there is certainly some danger of unequal reduction, but experience and practice, as in all other photographic manipulations, will make the process easy and safe. The reduction seems more certain if the negative has not been dried, and it is not necessary that it should have been thoroughly washed, but the greater part of the fixing solution should have been removed from the film. If it is necessary to reduce a negative that has been dried or even varnished it can be done, but the *whole* of the varnish must be removed and the film softened by soaking, for an hour or so, in water. After reducing in this way it is advisable to refix the negative, to remove any ferrocyanide of silver that may be undissolved.

When the negative is not hard, but too dense generally, so that it would print slowly, the same reducer will put matters right, but it should be used a great deal weaker, and the operation will take perhaps a minute or more. A general reduction of density then seems to take place, lights and shadows in about the same proportion. The negative should be removed from the dish from time to time during the process, and rinsed under the tap and examined for density. It is probably not necessary to refix after this method.

Sometimes it is necessary to reduce the shadows of a negative without touching the high-light, as, for instance, a copy of a line-drawing in which from over-exposure the fine lines are obscured. Again the ferricyanide comes in, but it must be very diluted this time, and the process may take three or four

minutes. Now, the shadows seem to be reduced most, and the high-lights appear to be affected but little, if at all. The same strength of solution is very useful for clearing lantern slides, especially when carbonate of ammonium has been used in the developer, as it sometimes leaves a brownish yellow deposit all over the film. This will generally yield to the weak reducer, without affecting the general density of the slide, in any appreciable degree. I usually judge the strength of the solution by its colour: not very scientific, again; but, fortunately, photography, like tailoring, has not yet been reduced to the level of an exact science. I should not advise any one to make a first attempt on a valuable negative, but to experiment with a few wasters, for if other photographers are like myself they will have plenty to work upon.

But perhaps my chief use of the Howard-Farmer reducer is for local reduction, and here I think it is without a rival. For this purpose it should be used neither so strong as to act very quickly, nor so weak as to reduce slowly. It is not suitable for very small spaces; Globe metal polish and wash-leather is better for them. But for fairly large patches it is excellent, and may be applied with a camel-hair mop or a tuft of cotton-wool. For my own part I prefer the fingers, using three fingers for large patches, two for smaller ones, and one finger for smaller still; cotton-wool sometimes leaves streaky marks, and puts on so much solution that it runs where it is not wanted, but the fingers do not leave streaks and put on just enough, and not too much. During the process the negative must be rinsed every few seconds, and the progress of the reduction examined. This method is useful for emphasising some principal objects by reducing the strength of more subordinate ones, and so on, for removing halation in interiors, and for taking down the harsh whites in landscapes, where a piece of road runs out at the bottom of the negative, and for a host of other things. Then it has another use, for removing those iridescent stains that appear when plates are stale and have been developed with ammonia; for this purpose it may be used so weak that it will not affect the image. The reducer that has been used for plates will remove those nasty stains that come on dishes that have been used for pyro and ammonia. In fact, to parody the well-known puff, no dark-room is complete without it.

HAROLD BAKER.

THE DEPOSITION OF FOG BY ELECTRICITY.

At a recent meeting of the Midland Institute Scientific Society Sir Oliver Lodge, Principal of the University of Birmingham, gave a most interesting demonstration of the deposition of smoke and fog by means of a discharge of electricity. He began by saying that the usual definition of fog, mist, or cloud, as vapour of water floating in the air, was incorrect, and that a better definition was "particles of water falling through the air," although the rate of falling was very slow, and sometimes checked by upward currents of air. An ordinary land fog might be described as a perspiration of the earth. Some twenty years ago Sir Oliver began his experiments at Liverpool, and found that if a warm rod was placed in a box filled with smoke, a clear or dust-free space was formed round the rod, and streamed upward above it. The early experiments were made with an ordinary cigar box, with a glass end, and filled with cigar smoke. A discharge of electricity was found to make the particles of smoke fall and leave the air quite clear. A practical demonstration was then given by filling a glass shade with the dense white smoke of burning magnesium, a current from a machine with two revolving glass plates was then discharged from a rod inside the shade, and in a few seconds the smoke became violently agitated, and condensed in white flakes on the sides and base of the glass shade, leaving the air

within quite clear. Sir Oliver Lodge then described how he had a tall mast fixed at the top of a high building in Liverpool, connected with a powerful electrical machine, and then waited for a fog to come. It was a long time before a sea mist appeared, and then he was away from Liverpool, but his assistant at once set the machinery to work, and found that a clear space of fifty to sixty yards was formed round the mast, and the fog was seen to be rolling in from all sides.

Sir Oliver Lodge brought the subject before the Dock Board, and suggested that it should be tried in the Mersey, especially on stationary light-ships, which would be able to keep an area clear of fog round them; but before anything was settled he left Liverpool for Birmingham, and the matter dropped.

There were, of course, practical difficulties in the way, one of them being the delicacy of the machinery for producing the current, and another the difficulty of insulating a current of such intensity as three million volts. The only practical means of producing such a current on a scale sufficient to have any effect was to use an alternating current, and then by means of a transformer raise the voltage to the necessary intensity, but an alternating current is useless for depositing fog. And there the matter rested for some time. When, however, the Cooper-Hewitt mercury-vapour lamp was invented, it occurred to Sir Oliver that by its means he could separate the negative and positive electricity and send them in different directions. A battery of small Cooper-Hewitt lamps was fitted up, and a high-tension alternating current was sent through them, and one pole was connected to the discharging rod in the bell jar of smoke, and the smoke was quickly deposited in flakes as before. A really practical method has, therefore, been evolved of depositing fog, but whether its use on a large scale is feasible is a question yet to be answered. The arrangement of a battery of mercury-vapour tubes for separating the poles of an alternating current is very ingenious. The current alternated from positive to negative three hundred times per second. The large Cooper-Hewitt lamp exhibited was extremely interesting. It gave a line of light four feet long, each half-inch of which appeared as brilliant as the ordinary arc-lamp used for street lighting, and the amount of current used was very small, being only three amperes. Unfortunately, the effect on the faces of the spectators is very ghastly, and resembles that of the sodium flame—an experiment most of us have probably made at some time or another. If any photographer wishes to see what his sitters would look like he has only to put a handful of salt in a saucer, pour some methylated spirit over, and take it in the dark-room and light it. A piece of vermilion sealing-wax looks like a bit of lead, and the faces with bright complexions look especially deathly. But for process work and printing such a light would be wonderfully cheap and very efficient.

Would it not be possible to devise an enlarging light with such a lamp by using a long glass tube somewhat in the shape of a gridiron, to illuminate the whole of a negative, and so avoid using a condenser? An enlargement from a portrait negative with a condenser is far inferior in its values to one from the same negative by daylight, the amount of the objectionable "working up" on the print in the latter is extremely small, so as to become little more than spotting. Such a lamp ought not to be expensive to make and to maintain. I beg to offer the idea to any one who feels inclined to try it.

For portrait work some means of introducing red into the light is necessary, unless friends of the sitter and all mirrors are removed from the studio. But as the light is so powerful the introduction of red into translucent screens ought to have but little effect on the actinic power of the light.

A STUDIO WORKER.

SOME POST-CARD STORIES.

[From "The Picture Postcard."]

SEEING how largely picture post-cards now enter into daily life, it would be strange if they were never connected with curious happenings, or the causes of comedies, or even the players of a part in tragedies. And, as a matter of fact, they have contributed so often to the material of real dramas that there is no need to draw upon the imagination for stories of thrilling human interest connected with cards. I propose, therefore, to draw on my stores of newspaper reports for the few stories I have space to tell; needless to say, they are all facts from real life.

My first story may be called a comedy, though it was by no means comical, but doubtless very painful for the chief persons concerned. It is about a young Italian couple and a bold, bad photographer. The lady was the daughter of a well-known Genoese painter, and she was engaged to be married to a rich and doubtless handsome young gentleman. Naturally enough, our fair heroine wished to have her portrait taken, and went to the studio of the photographer—the villain of the piece. Perhaps "villain" is too strong a word, and so we will call him the evil genius, for he did not intend to harm his sitter, although he was the cause of the trouble. It seems, then, that the young lady, who was very beautiful, made such an exquisite portrait that he reproduced her on and as picture post-cards. These were so pretty that very soon all Genoa was full of them. The consequence was disastrous, for the family of the hero so strongly objected to his marrying a "post-card girl" that, after several painful scenes, the match was broken off. The photographer contended that the young lady gave him leave to have her portrait reproduced, which she, of course, denied. Whether or not he had played on her vanity and really got her permission, is not for me to suggest; I only know that human nature is weak, that beauty is a fatal gift, and that the pretty lady lost her lover. Sordid truth compels me to add that this very modern young lady sought consolation to her wounded feelings by promptly suing the offending photographer for the substantial sum of £3,000 "as and for liquidated damages." Whether or not she got it, or any part of it, deponent cannot tell; all I can say is, she deserved compensation of some sort for her trouble and loss—perhaps she had her revenge by subsequently marrying the photographer!

My next story is a true tragedy of a post-card, for it embraces all the elements of love, elopement, theft, murder, and suicide. In the early part of this year, Friedrich Arndt, a book-keeper, of Magdeburg, stole £1,000 belonging to his employers. Most of this money he spent in presents for his pretty sweetheart, Elsie Senders. When the funds began to dwindle he persuaded Elsie to accompany him to Berlin, where, under an assumed name, they would begin a new life. They took a room at a well-known hotel in the centre of Berlin, and registered as "Herr Schneider und Frau." Unfortunately, "Frau Schneider" could not deny herself the pleasure of writing a picture post-card to some of her friends in Magdeburg. This put the police on the track of the errant couple, and one morning Arndt, or "Schneider," noticed that the police were in the hotel. When the guardians of the law approached his door, he put a revolver to the temple of poor, misguided Elsie, and shot her. He then killed himself. Elsie was just able to tell the story of the tragedy before she died. Alas for Elsie, alas for Frederick, and alas for poor human nature! It is a sad story, and the only detail which differentiates it from dozens of similar tragedies, is the simple fact that a picture post-card was the immediate cause of the dénouement of the tragedy.

Among other crimes connected with post-cards, I remember the case of a foreign criminal who was arrested in the town to which he had fled by a policeman who recognised him through having seen his portrait on a post-card. Quite recently, the Armenian who murdered three of his compatriots, and then committed suicide, was identified by the assistant at a shop where he had bought a picture post-card just before the fatal deed. Less tragic, but very painful to the Royal Family of Belgium, must have been the post-cards offered by hawkers outside the Cathedral of Brussels after the requiem mass for the repose of the soul of the late Queen of

the Belgians. These cards bore portraits of the King and Queen and their children, and the hawkers, making capital of the well-known family disagreements, cried: "Buy what no one has ever seen, the Royal Family reunited."

HAL HALIDAY.

THE LATE MR. MARSHALL WANE.

MR. MARSHALL WANE, the well-known photographer, passed away suddenly, but very peacefully in his sleep, at his residence, 7, Holborn Terrace, Glasgow, on Monday, 14th December. He was in good health almost to the day of his death, which was most unexpected. Mr. Wane was born in 1833, and thus was seventy years of age. He was devoted to his profession, and first began to photograph in 1852 as an amateur, when he was nineteen years of age. Self-taught from the beginning, and always very ingenious, he made his first camera out of a cigar-box, and a lens out of a mustard tin, and a magnifying glass. As is usually done by amateurs, he experimented on his friends in the garden, with a blanket as a background; when it rained an umbrella was put up. The only time the young amateur had was during his lunch hour, and he was often so engrossed in his work that he had to run all the way to the office—two miles away. These early attempts were glass positives, only a few inches in size. Rapidly becoming proficient, there was such a demand from friends for portraits made by the new art, that all his spare cash was spent in photographic material; so a small charge was made to cover expenses. The money thus made was put into a child's earthenware money-box, which had to be broken when filled. Full in a very short time, it was found to contain sufficient to purchase an up-to-date outfit from London. This was done, and with superior appliances his work so much improved, and was so much admired, that he decided to start business as a professional. Accordingly, he began in 1854, at Knutsford, and, successful from the start, was enabled to build a studio in Douglas, Isle of Man, in 1858, where he remained twenty-three years.

Married in 1861, Mr. and Mrs. Wane's married life has been an ideal one. Up to a year ago, Mrs. Wane has always been associated with Mr. Wane in the business, and was nearly as well known to their clients as he was—in every sense of the word she has been his "partner" through life, and her woman's wit and good advice has proved invaluable on many occasions.

In 1879 Mr. Wane was induced by the late Lord Loch, who was then Governor of the Island, and several influential friends to go to Edinburgh, where he remained until 1902, when he received an offer for his business by a company which he accepted. In the following year he opened a studio at 518, Great Western Road, Glasgow, with a view to leaving it to his two sons, after giving them the benefit of his well-known name; also his invaluable advice and experience. He had just accomplished his last wish, "To give his boys a fair start," when he was called away. The business will be carried on under the name of "Marshall Wane" by his two sons, Mr. H. P. Wane, a medallist and technical expert, and Charles Marshall Wane. Mr. Wane, fond of all outdoor sports, was a good swimmer and a capital shot, and could cycle his fifty miles a day easily; he was the oldest cyclist in Scotland, having been one for nearly forty years. He could play a good game of billiards, and was fond of a game of whist. He was very fond of reading. Mr. Wane was known by a large circle of friends, and to quote one of them—"To know him was to love him and esteem him."

THE KEARTON NATURE PHOTOGRAPHS. — We understand that the Brothers Kerton have arranged to hold an exhibition of enlarged photographs of birds, beasts, reptiles, and insects, at the Modern Gallery, Bond Street, W., from the 2nd to the 12th of January inclusive. The Gallery will be open from 10 a.m. till 9 p.m., and Mr. R. Kerton, F.Z.S., will deliver limelight lectures to children each afternoon, and to adults in the evening.

WHAT PHYSICAL CHEMISTRY HAS DONE FOR CHEMISTRY.

[Abstract of a paper read before the Chemical Section of the Franklin Institute.]

PHYSICAL chemistry has furnished us with several generalisations which have greatly modified our methods of dealing with chemical phenomena. Among these may be cited the Theory of Electrolytic Dissociation, the Law of Mass Action, Faraday's Law, the basis of chemical valence, and the Phase Rule. Of these generalisations time will permit us to consider only one or two, and we can only make a few applications of the most important of them all—the Theory of Electrolytic Dissociation. A word or two in reference to the origin of the theory:—

Osmotic Pressure.—When a solution of any substance is brought in contact with the pure solvent, or with a solution of different concentration, at the surface of contact of the two solutions there exists a pressure which tends to drive the dissolved substance from the region of greater to the region of lesser concentration. This is known as osmotic pressure. The first to measure the magnitude of this pressure was the botanist, Wilhelm Pfeffer, who found that salts gave a greater osmotic pressure, for equivalent concentrations, than solutions of substances like cane sugar.

Origin of the Theory of Electrolytic Dissociation.—It remained for Van't Hoff to point out that the electrolytes in general—acids, bases, and salts—exerted a greater osmotic pressure than the non-electrolytes. He also showed that osmotic pressure is a property which depends only upon the number of parts of the dissolved substance in a given volume of the solvent, and not upon the nature of the parts. Since osmotic pressure depends only upon the ratio between the number of parts of the dissolved substance and the number of parts of the solvent, and since electrolytes exert an osmotic pressure that is greater than can be accounted for on the basis of the existence of these substances in the molecular condition, we are forced to the conclusion that the molecules of electrolytes are broken down in solution into parts. These part molecules are called ions.

I cannot take up here the evidence bearing upon the theory of electrolytic dissociation, since it would lead much too far. Suffice it to say that the experimental evidence, as far as it has been established in a trustworthy manner, is practically unanimously in favour of the theory, and the amount of such evidence already at hand is simply overwhelming. The theory of electrolytic dissociation is as well established as most of our laws in science, and is to-day almost universally accepted by the leading chemists and physical chemists throughout the world.

Neutralisation of Acids and Bases.—Let us now see what the theory has done for chemistry. Here again we can take up only a few of the many applications of this most important generalisation. Take a class of chemical reactions that are more or less familiar to every one—the neutralisation of acids and bases. It has long been known that when an acid is brought in contact with a base, both are neutralised, and when the solution is evaporated a salt is obtained. Since a different salt was obtained with every acid and base employed, we had as many new phases of the problem of neutralisation as we had acids and bases to react.

This whole subject has been beautifully unified and simplified by means of our theory. Take the neutralisation of hydrochloric acid with sodium hydroxide. Hydrochloric acid in dilute solution is a mixture of hydrogen ions and chlorine ions:—

Sodium hydroxide in dilute solution is a mixture of sodium ions and hydroxyl ions:—

When these solutions are brought together we have:—

What takes place and all that takes place in the above case is the union of the hydrogen ion of the acid with the hydroxyl ion of the base, forming a molecule of water. The anion of the acid, chlorine, and the cation of the base, sodium, remain after the process of neutralisation in exactly the same condition as before neutralisation.

took place, and a salt is formed only when the solvent which dissociated the salt into its ions is removed. We may now discuss the subject of neutralisation in general. We may represent any acid by:—

is the anion, which differs in composition for every acid, and the cation hydrogen which is common to every acid. Similarly, we may represent any base by:—

is the cation of the base. Its composition varying with every base, and hydroxyl is the anion common to all bases. When any base reacts with any acid, we have:—

Water is always formed, and the anion of the acid \bar{R} , and the cation of the base $\overset{+}{R}$, remain in the solution after the process of neutralisation in exactly the same condition as before neutralisation took place. In order to obtain the salt the water which holds the ions apart must be removed.

Neutralisation, then, in terms of our theory consists in the formation of a molecule of water from a molecule of the acid and a molecule of the base, and in nothing else. One process of neutralisation is, therefore, exactly the same as any other process of neutralisation, regardless of the nature of the acid or the nature of the base involved. If this is true it is very important, since it refers all the processes of neutralisation to a common cause—the union of the hydrogen ion of the acid with the hydroxyl ion of the base.

Thermoneutrality of Salts.—Another application of the theory of electrolytic dissociation in thermochemistry is interesting and important. It has long been known that when dilute solutions of neutral salts are mixed there is no thermal change—heat is neither liberated nor absorbed. This is the well-known law of the thermoneutrality of salts. While the fact was established beyond question, and various suggestions had been made to account for it, it was generally conceded that no one of these was at all satisfactory. The explanation to-day is very simple. Take the two salts, potassium chloride and sodium nitrate; a dilute, aqueous solution of potassium chloride contains only potassium ions and chlorine ions; a dilute solution of sodium nitrate contains sodium ions and nitric ions.

When the two solutions are mixed we have in the mixture potassium and sodium cations and chlorine and nitric anions, and nothing else. In a word, we have exactly the same ions in the mixture as in the solutions before they were mixed. There being no chemical change, there should be no thermal change, and such is the fact. The law of the thermoneutrality of salts could have been predicted from the theory of electrolytic dissociation, had it not been discovered long before the theory was discovered.

HARRY C. JONES

THE Nottingham Camera Club's exhibition will be held in the Mechanics' Lecture Hall, Nottingham, on Wednesday, Thursday, Friday, and Saturday, March 9th, 10th, 11th, and 12th, 1904.

ROYAL Photographic Society.—On January 5th, 1904 (Tuesday), the first of the series of Practical Demonstrations of Printing Processes will be given. The subject will be Silver Printing by Mr. Henry W. Bennett. Synopsis—(1) Type of negative. (2) The choice of a paper. (3) Storage of paper and prints. Printing:—General precautions—estimating, correct exposure, etc. Preliminary washing and toning. Choice of a toning bath. Precautions necessary to ensure successful toning. Estimating final colour. Fixing and final washing. Causes of fading. Aids to permanence. Mr. J. T. Ashby will occupy the chair.

Commercial & Legal Intelligence

MR. PHILIP G. HUNT has taken larger premises at No. 100, Deansgate, Manchester, and invites the wholesale, and trade, to send for samples and prices of collotype, plain and coloured, also real photograph post-cards, which are executed from his own or customers' originals.

ELITE PORTRAIT COMPANY, LIMITED.—The above-named company has been registered with a capital of £1,000 in £1 shares. Object, to adopt an agreement with E. I. Davis for the acquisition of the business of the Elite Portrait Company, of 267, High Holborn, and to carry on the business of manufacturers of and dealers in photographic material and apparatus, photographs, pictures, prints, and engravings, publishers of works of art, photographers, etc. No initial public issue. E. I. Davis is the first managing director, with power to appoint other directors. Remuneration of managing director, £350. Registered office, 267, High Holborn, W.C.

CAMPBELL-GRAY AND EDWARDS-DUNCAN, LIMITED.—The above-named company has been registered with a capital of £3,000 in £1 shares. Object, to adopt agreements (1) with A. J. Campbell and C. E. Gray, and (2) with P. T. Edwards and C. W. W. Duncan for the acquisition of the businesses of photographers, process block makers, dealers in photographic materials and etchings, art publishers, illustrators, designers, draughtsmen, engravers, etc., carried on by the said A. J. Campbell and C. Gray at 17, Cheapside, E.C., and by the said P. T. Edwards and C. W. W. Duncan at 173, Fleet Street, E.C., and to carry on the said undertakings. No initial public issue. The first directors (to number not less than two or more than seven) are A. J. Campbell, C. E. Gray, P. T. Edwards, and C. W. W. Duncan. Qualification (except first directors), £500. Registered office, 17, Cheapside, E.C.

MR. JAMES A. SINCLAIR, of 54, Haymarket, London, S.W., writes: "Some few weeks since, when announcing to you my resignation as Manager to Messrs. Ross, Ltd., of Cockspur Street, S.W., I mentioned that I was inaugurating a new business at 54, Haymarket, S.W. The extensive and necessary alterations to the building are now complete. The policy which I have pursued in the past, of only recommending articles of undoubted quality and reputation, will be maintained, and I shall always be glad to help customers with advice regarding any of their requirements. The Departments of my new firm will be as follows:—Photographic Materials: The usual photographic sundries and chemicals will be sold at lowest prices. A speciality will be made of hand cameras, by the leading makers, at prices ranging from £1 to £50. A dark-room is available for customers. Optics: Ross, Voigtlander, and Zeiss prism binoculars are stocked, and the various makes may be compared. Naval and military telescopes, as well as opera and field glasses, will be recommended on their merits. Eyesight Testing and Spectacle Making: In this department we have engaged the assistance of Mr. H. C. Patey, F.S.M.C., who is qualified by passing the highest examination of the Spectacle Makers' Company. We reserve a special room for this important work, and test for all errors of refraction in myopia, hypermetropia, presbyopia, astigmatism, etc., and supply accurately-ground lenses and pebbles in perfectly fitting frames. Where disease is found, or where we consider it advisable for the patient to consult an oculist, we do not hesitate to say so. Oculists' prescriptions are carefully made up, particular care being taken that the spectacles or eye-glasses supplied allow the lenses to come into the correct position before the eyes."

THE "FREE PHOTO" DODGE.—At a sale on December 28th a young man named Michael Finnegan, of Claremount street, Chorlton-on-Medlock, who is an agent of the Empire Art Co., Shakespeare Street, Manchester, was summoned for assaulting Mary Ann Garner, King Street, Sale, under peculiar circumstances. Mr. Desquesnes, who appeared for the complainant, said the case was one of assault arising out of some transactions relating to a portrait which complainant's husband agreed to purchase some time ago. These people sent round agents professing to supply a portrait of some member of the family absolutely free of charge, but there was a "slight" condition

attached that they should pay for the frame. When the complainant's husband entered into the transaction, all he was told was that he would have to pay 1s. weekly. On the date of the alleged assault, December 19th, defendant took the picture to the complainant's house. She examined the frame and said it was rubbish. In the result, defendant lost his temper, and in the struggle to get possession of the picture she was banged against the door, and when the police arrived she was found to be bleeding from a wound in the hand. Mrs. Garner said the defendant demanded 7s. 6d., but she told him the agreement was for 1s. per week. He told her it was a matter of their fighting the police in Manchester. Police-constable Watson said when he arrived Mrs. Garner had been badly knocked about. Defendant said his instructions from the company were to take back the picture if the balance was not paid. He declined to be kept a prisoner in the house. The Chairman (Mr. George Rooke) said the real question was that of assault. Defendant replied that they were both injured, and that it was her own fault. Mr. Desquesnes produced the "picture," which he thought would be dear at 1s. The Chairman said the Bench were unanimous in convicting, and fined the defendant 20s., including costs.

THE Civil Service Motor and Cycle Agency, Limited.—The Report of the Directors of this Company (proprietors of the Service Photographic Society) states that the trading for the twelve months ending September 30th, 1903, has shown a gross profit of £3,839 10s. 1½d. (comparing with £3,110 2s. 1½d. in the previous year), and a net profit of £977 9s. 1d. The amount brought forward from last year, after deducting income-tax, interest on deposits, etc., was £57 0s. 3d., which amount, added to the profit on the past year's trading, gives an available balance of £1,054 9s. 4d., and, after payment of the interim dividend on Preference holdings of £50 and upwards, leaves a balance of £975 8s. 9d. to be disposed of. The Directors propose to devote this to the payment of the balance of the 6 per cent. dividend on the Preference shares, to pay 5 per cent. on the Ordinary shares, to carry £250 to reserve (increasing that account to £1,000), and to carry forward £50 12s. 7½d. The profit has been arrived at after making a proper allowance for depreciation, bad debts, and rebates for prompt payment of easy payment accounts, and considering the extremely unfavourable conditions of the past season, the Directors have no doubt that the shareholders will consider the result satisfactory. In the last Report the Directors called attention to the fact that it was proposed to devote more attention to the motor business. In furtherance of this policy they have during the year taken additional premises in Featherstone Buildings, which are conveniently near to 292, High Holborn, and well adapted to the present requirements of the Motor Department. The Directors consider that the results already attained have fully justified this step, and believe that this department of the business can be made a very profitable one. Some of the items of expense in the Profit and Loss Account have shown an increase, but in view of the initial expense in connection with the motor business, the Directors do not think that the increase can be regarded as unsatisfactory, and they hope that, under normal conditions, the percentage to turnover will show a decrease during the coming year. It is with very great pleasure that the Directors call attention to the fact that without any special advertisement, and without any special item of expense being brought into the accounts, 1,512 Preference shares have been applied for during the year. There only remained at the date of the accounts 274 of these shares still unapplied for, and as the Directors hope that the steady development of the business during the coming season will make further money desirable, they are giving notice of a proposed increase in capital, and trust to receive the support of the shareholders in getting the new shares applied for. The Service Furnishing Society, Limited, is now on a dividend-paying basis, the profit on trading during the past year being a very satisfactory one, and your Directors have every confidence that the "Interest from Investment Account" will show a steady and continued increase.

"PICTURESQUE NORWAY" is the title of a series of post-cards issued by the well-known photographic publishing house of Valentine. The work is entirely executed at Dundee, and a color process is employed for the impressions, which are singularly charming and effective.

Exhibitions.

THE KEARTON EXHIBITION.

THE Kearton Nature Photographic Exhibition, a collection of pictures of birds, beasts, reptiles, and insects, will be held from January 2nd to 12th inclusive, at the Modern Gallery, 175, Bond Street, W. The Exhibition will contain enlargements of such photographs as A Trout under Water, A Curlew standing by her Nest and Eggs, A Pair of Common Snipes sitting side by side covering their Chicks, A Great Crested Grebe on her Nest, Rabbits at Play, Leverets in their Forms, A Pied Blackbird, Butterflies Asleep with their Wings covered with Dewdrops, A Grass Snake basking in the Sun, An Adder or Viper, A Stoat trying to drag away a Rabbit it has just killed, Owls Asleep and Awake, A Song Thrush Photographed whilst at Roost by Flashlight, An Adult Cuckoo, A Corncrake on her Nest, The Exceedingly Shy Water-Rail at Home, A Red Grouse on her Nest, A French or Red-Legged Partridge on her Nest made beneath a Broken Plant Pot, A Woodpecker running up the Trunk of a Tree, Young Eagles in their Eyrie, Sea Birds at Home, and a great number of other rare and interesting creatures photographed amidst their natural surroundings. The programme is as follows:—Jan. 2—Open from 10 a.m. till 9.30 p.m.; Children's Lecture, 3 to 5.40; Evening Lecture, 8 to 9; Jan. 4—Same as Jan. 2; Jan. 5—Same as Jan. 2; Jan. 6—10 a.m. to 6 p.m. (Afternoon Lecture only); Jan. 7—Same as Jan. 2; Jan. 8—Same as Jan. 6; Jan. 9—Same as Jan. 2; Jan. 11—Same as Jan. 2; Jan. 12 (Last day)—same as Jan. 2.

THE BIRMINGHAM EXHIBITION.

THE Birmingham Photographic Society's 19th Annual Exhibition will be held at the Galleries of the Royal Society of Artists, New Street, Birmingham, from Saturday, February 27th, to Saturday, March 5th, 1904. The Council call the attention of exhibitors to the fact that these galleries are probably the most convenient in the country for the effective display of photographic work. It is hoped that this Exhibition will meet with such support from all artistic workers as will make it the most successful ever held by the society. The judges will be Messrs. W. R. Bland, F.R.P.S., R. Catterson-Smith (Head Master School of Art, Birmingham), J. H. Gear, F.R.P.S.; and the selection-committee, Messrs. W. T. Greatbatch, F.R.P.S., Harold Holcroft, M.A., F.R.P.S., Bernard Moore, J. Cruwys Richards. The following are the particulars of the classes:—Open Classes.—A. Framed Pictures (any subject). B. Lantern Slides (any subject; not more than 12 can be received from one exhibitor, and they will be judged separately, not in sets). Members' Classes.—C. Framed Pictures (any subject). D. Novices' Section; Framed Pictures, any subject or size, by those members only who have never taken an award (except certificate of honourable mention) in any photographic exhibition (survey work excepted) or exhibited at the Royal Photographic Society's Exhibition or Salon. E. Lantern Slides; any subject; not more than 12 can be received from one exhibitor, and they will be judged separately (not in sets). The awards will be silver and bronze medals and certificates of honourable mention. The judges will have absolute discretion as to awards. The Silver Challenge Cup will be awarded to the member gaining the highest total of awards. A silver medal counts three; bronze, two; certificate, one. This challenge cup will be held by the winner for one year, and his name will be engraved on it. Present holder, Mr. J. Cruwys Richards.

Rules and Regulations.—1, Wall Space: No entrance fees will be charged, but all pictures and slides will be submitted to the Selection Committee, who reserve the right to reject any exhibit; all exhibits sent in will pass before the judges. 2, Entry Forms: Every exhibit must be correctly described on the entry form, which is to be returned to the Exhibition hon. sec., L. Lloyd, The Hollies, Church Road, Moseley, Birmingham, not later than Monday, February 22nd. 3, Delivery of Exhibits: Exhibits will be received on Monday and Tuesday (last day), February 22nd and 23rd. They should be

addressed to the Birmingham Photographic Society, Royal Society of Artists, New Street, Birmingham. Carriage must be paid by the sender. 4, All photographs must be framed (except in case of exhibits from abroad). Ox.ord frames will not be accepted. To the back of each frame must be affixed a label bearing the name and address of the exhibitor and the title of the picture, and price if for sale. 5, Lantern Slides: All slides will be judged by limelight. They must be standard size, 3in. by 3in., and correctly spotted. Each slide must bear upon its face the title and exhibitor's name, which should also appear on the box containing the set. 6, An Award List and Catalogue will be posted to all exhibitors as soon as possible. 7, Sales: Sales must be effected through the society's officers, and are subject to 10 per cent. commission. It is understood that the price in every case is for the original picture and includes frame. The Committee would esteem it a favour if exhibitors would kindly say if a duplicate can be supplied. 8, Return of Exhibits: Exhibitors will greatly assist the Committee by giving full particulars as to the return of pictures. Those for return by post must be accompanied by stamped and addressed label, and an addressed card should be enclosed in those packages to be returned by rail. 9, Exhibits must be the unaided work of the exhibitor. Any breach of this rule will lead to the rejection of all work sent in by the offender. 10, Care of Exhibits: Every possible care will be taken of exhibits, but the Council cannot accept any responsibility for loss or damage. 11, Liverpool Exhibition: Arrangements can be made for forwarding pictures direct to this exhibition, which opens on March 25th, 1904.

FORTHCOMING EXHIBITIONS.

January 5-9.—Sefton Park Photographic Society. Particulars from H. E. Cubley, 3, Langdale Road, Liverpool.

Feb. 10-13.—The Longton and District Photographic Society. Hon. secretary, T. Mottershead, 43, Stafford Street, Longton, Staffs.

February 13-27.—Scottish National Photographic Salon. Exhibition Secretary, Alex. Mackenzie, 42, Scott Street, Perth.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd, Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Chadwell, Essex.

March 5-12.—Brechin Photographic Association. Hon. secretary, J. Kirk, 1, Infirmary Street, Brechin.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

Mr. S. HERBERT FRY, of 12, South Villas, Camden Square, London, N.W., sends us a copy of his almanac for 1904. The portrait of a little child, in carbon, entitled "My Lady Dolly," adorns the almanac, copies of which may be had gratis by any professional photographer on application to Mr. Fry.

WELLCOME'S Photographic Exposure Record and Diary for 1904.—One feature of the 1904 issue of Wellcome's Photographic Exposure Record and Diary is the wallet binding which is supplied with the 1s. books in place of the elastic binding previously used. The book has been revised and some new matter has been added, including a table for contact printing by artificial light. The relative speeds of plates have again been given attention. The 2s. book has been reduced to 1s. 6d. net. There are, as usual, two editions—the Northern Hemisphere edition, containing tables giving correct exposures for all countries north of the Tropic of Cancer; the Southern Hemisphere and Tropical editions covering all countries lying in the sphere indicated by its title. Most chemists and photographic dealers hold stocks or can obtain copies of the book by return of post. It is on sale at the book-stalls in London and the provinces, and is also obtainable of Messrs. Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
1.....	West London Photo. Society ...	<i>Printing Methods.</i> Mr. G. F. Blackmore.
1.....	Watford Photographic Union...	<i>The London Photographic Exhibitions.</i> Mr. H. Langford Lewis.
4.....	Ilford and District Photo. Soc.	<i>Wet Collodion.</i> Mr. W. T. Wilkinson.
4.....	Bowes Park & Dist. Photo. Soc.	<i>Conversation and Members' Exhibition.</i>
7.....	Camera Club	<i>Walled Towns in England.</i> Mr. C. H. Bothamley, F.C.S.
7.....	Bath Y.M.C.A. Camera Club.....	<i>Stereoscopic Photography.</i> Illustrated.
7.....	Watford Camera Club	Annual General Meeting and Election of Officers.
7.....	Southport Photographic Society	<i>A Cheap Telephoto Lens.</i> Mr. R. W. Woods.
7.....	Liverpool Amateur Photo. Asso.	<i>Films and Papers, Cameras, Cosin, for Daylight Development.</i> Mr. W. F. Slater.
7.....	Hull Photographic Society.....	<i>Picture Making by Photography.</i> Mr. Chas. W. Hastings.

ROYAL PHOTOGRAPHIC SOCIETY

PROCEEDINGS OF COUNCIL: THE FELLOWSHIP.

THE Council, desiring that the possession of the Fellowship shall be the highest evidence of efficiency in photography and its many applications, have passed over no proposals that seem to promise an opportunity and a method of elevating its status and improving its administration. The standard of qualification has been steadily raised during several years and no effort has been spared in the endeavour to arrive at a true estimate of the fitness, in every respect, of the candidates who have submitted their claims. The Council have recently concluded an inquiry into some proposals which had for their aim the improvement of the Fellowship in the directions indicated, but, after a long and careful consideration, they have felt it necessary to reject the chief feature of the proposed alteration. Briefly stated, the proposal was to entrust the admission of candidates for the Fellowship to the whole body of the Fellows. The Council have been able, however, to approve one or two suggestions on matters of detail and administration, which are indicated below.

It has been resolved:—

- (1) That the election of Fellows remain with the Council.
- (2) That two committees be appointed, one to consider qualifications on the scientific side of the art, and one to consider qualifications on the pictorial side, such committees to receive and consider the applications for the Fellowship and report thereon to Council.
- (3) That the two committees consist each of nine Fellows or Members of the Society who shall be appointed by the Council, one-third of each committee to retire annually by rotation and be eligible for reappointment, the three retiring members in the first two years to be decided by ballot.
- (4) That the Council fill any vacancies on the committee that may arise.
- (5) That each committee appoint a chairman. That at their meetings six form a quorum on each committee. That the chairman of each committee appoint another day for meeting in the event of no quorum being formed.
- (6) That applications for the Fellowship be recommended by two Fellows of the Society, as proposer and seconder, such recommendation to be taken as expressing only the personal or social eligibility of the candidate, the question of technical or pictorial qualification being left to the committees.
- (7) That there be two elections of Fellows in every year, one on the second Tuesday in January, and one on the second Tuesday in June, and that the applications be received by October 1st, and March 1st respectively, and that the committees meet for the first time on or before October 8th, and March 8th respectively, as near as may be.
- (8) That at the Meetings of Council when the discussion of the applications takes place, the chairman of each committee or, in his unavoidable absence, a member named by him shall be present to speak upon the applications if necessary.

(9) That the existing standing orders of Council, respecting the election of Fellows, be confirmed, except where modified by the foregoing resolutions.

The Council give notice that these amended regulations will take effect as from March 1st, 1904, and that applications at present in hand will be dealt with under the existing regulations.

THE PROGRESS MEDAL.

No nominations for the Progress Medal having been submitted to the Council by its members, there will be no award during the year 1904.

DECEMBER 22nd.—Mr. H. W. Bennett introduced a new method of sensitising carbon tissue. One of the most charming features of the carbon process, said the lecturer, was the facilities it afforded for printing in so many different and beautiful colours. The worker in a comparatively small way, however, was met by serious difficulties when he wished to keep a small stock of sensitised tissue. The obvious remedy was to sensitise the tissue oneself, as it might be required; but unless the drying arrangements were perfect, the sensitising in the ordinary way proved far from satisfactory. By the new method even the smallest quantities of tissue could be sensitised and dried in any ordinary room; the products of gas combustion would not affect it, and beautifully fine gradations might be obtained in the prints. The sensitising solution was as follows:—Potassium bichromate, 1 oz.; citric acid, $\frac{1}{2}$ oz.; water, 50 oz.; ammonia, about $\frac{3}{4}$ oz. The proportion of ammonia required might vary slightly, but sufficient should be used to change the colour of the solution to a distinct lemon yellow. This solution was suitable for all makes of tissue, except that in the case of Wellington and Ward's tissue only about one-third of the proportion of ammonia was required. The drying might be carried out without any special precautions beyond the darkening of the room, and would take from four to about seven hours. Tissue sensitised according to this method showed no tendency to break, and would allow the backing paper to be stripped off quite easily. The citric acid had considerable effect in regard to the gradations of the print, and the proportion could be increased or decreased as found desirable. The printing took about 50 per cent. longer than usual; but that was a very small disadvantage in face of the fine gradation obtainable. All makes of tissue appeared to be equally sensitive when treated in this bath. Some very fine prints made with tissue sensitised by this new method were shown.

In reply to some inquiries, the lecturer said that the keeping qualities of the solution appeared to be very good, provided it was carefully made up and distilled water used. Some of the prints shown were made with solution which had been mixed up several weeks. He usually sensitised the day before printing, and found no special precautions in regard to storage necessary, beyond keeping the tissue under pressure, and protected from the light and air.

At the same meeting, Mr. T. Thorne Baker, F.C.S., read a paper on "Combined Development and Fixing." Edinol and hydroquinone as reducing agents appeared to give more promising results than other developers, and from 3 to 25 per cent. of hypo was used in the combined solutions. Of course the hypo favoured fog, and the lecturer in his modesty, spoke of almost all his experiments proving failures; but some lantern slides which were shown, made from negatives developed and fixed simultaneously, were certainly all but perfect. The subject was admittedly a complicated and difficult one, especially as it was necessary to adjust the rate of development to the rate of fixing.

GLASGOW AND WEST OF SCOTLAND AMATEUR PHOTOGRAPHIC ASSOCIATION.

DECEMBER 22nd.—For several years it has been the custom of the Edinburgh and the Glasgow and West of Scotland Associations to exchange lecturers, and in accordance with this arrangement the Western body had on 21st ult. the privilege of hearing one of the excellent papers for which the Edinburgh Society is enviably famous. Councillor McArthy, the Edinburgh President, was the lecturer, and his subject was "The Royal Mile: the Castle to Holyrood." The

district of Edinburgh described teems with buildings which have borne their part in Scottish history, and Mr. McArthy was able to show numerous quaint and picturesque views of these old-world buildings. They are fast giving place to modern structures, but fortunately the Survey Section of Edinburgh Photographic Society has been able to secure records of many that have disappeared. A deputation of office-bearers from the Edinburgh Society, who accompanied their President, were charged with messages of hearty goodwill to their Western brethren. The joint excursion, which proved so successful last summer, will be repeated this coming season.

THE RETURN TO THE WAR-PATH.

SIGNED "P. H. E.," the following review of Mr. Douglas English's book, "Wee Tim'rous Beasties," is published in the November number of the "R. P. S. Journal":—"The half-tone block is indeed a mixed blessing; for commercial and purely scientific publications its uses can scarcely be overrated, but for decorative purposes it has lowered our illustrated papers and many of our books into a gloomy abyss of dull mediocrity that can appeal only to the Philistine, and for this reason we regret that such an excellent and unpretentious book as Mr. Douglas English's "Wee Tim'rous Beasties" should be illustrated by this art-strangling process, for his wonderful photographs of these small fry certainly deserved to be rendered in photography. His photographs have been taken with great patience and with an eye to composition and naturalistic effect that places the bulk of them far above the crude work of the usual photographic animalier. At times, however, we wonder if orthochromatic plates were used, or whether defects of tone-value are due to reproductive or printing processes, and we should have preferred the omission of the puerile pen and ink additions on page 143. Of late years the Press has gravely given forth columns of the superficial bleat of the unscientific and often uneducated "nature-loving journalist"; scribbles rarely read, though nearly always dubbed in illiterate journalese as "charming," "full of keen observation and a love of nature," etc. But there are signs that even the groundlings are growing weary of this spurious "natural history," and require something with solid evidence of original observation or with the adornment of graceful imagination, though how much a writer of scientific matter should use his imagination is a disputed point. Mr. Seton Thomson has used his freely—too freely we think. Mr. Douglas English, too, shows imagination in his text, and the result is a series of articles in every way superior to the deadly dull "cataloguing" of the Jefferies school, and the disingenuous bleat of the journalist. But to excel as a literary artist we think Mr. English should write with greater vigour—in a word, use the particular for the general, and weigh more carefully the value of his words, as well as employ the pruning-knife more freely, as witness such a pleonasm as "congestive inflammation" or such a vulgarism as "frivolling." After a rough indication on general lines of the flaws in his work, we have much pleasure in commending "Wee Tim'rous Beasties" to everybody interested in the humbler forms of animal life, and we congratulate Mr. English both on his photography and literary work as well as on the really clever way in which he has made his photographs illustrate the text—always a difficult matter with photography. This is a book to buy for every "wee tim'rous" *homo sapiens*.

THE manufacturers of Busch lenses are desirous of obtaining possession of a number of prints or negatives taken with Busch lenses. They are required for advertising purposes, and must consist of local scenery and street scenes, seascapes, and shipping views. The Company are prepared to purchase such pictures as are considered suitable, and it is understood that the purchase secures to them the right of reproduction and copyright. In sending in prints or negatives full particulars should be given of the subject of the photograph and particular kind of Busch lens used, with detail as to aperture and exposure, etc. The users of Busch lenses are requested to forward specimens of their work to Mr. Henry F. Purser, or the Busch Camera Co., 35, Charles Street, Hatton Garden, London, E.C.

Patent News.

The following applications for patents were made between December 14th and December 19th, 1903:—

Films.—No. 27,353. "Improvements in photographic films." Joseph Hart Balfour.

Packing Boxes.—No. 27,354. "Improvements in or relating to packing boxes for photographic plates and the like." (Hugo Fritzsche, Germany.) Alfred Julius Bout.

Picture Carriers.—No. 27,484. "Improvements in processes of manufacturing photographic picture carriers." Josef Edler von Slawik.

Apparatus.—No. 27,791. "Improvements in photometric apparatus." George Careless Trewby.

Printing Frame.—No. 27,829. "Photographic printing or copying frame." Complete specification. Ludwig Meir.

Post-Cards.—No. 27,831. "Improvements in sensitised cards for the production of picture post-cards or the like." Complete specification. Ludwig Meir.

Apparatus.—No. 27,835. "Improvements in photographic apparatus." John Henry Hill Duncan, Graydon Poore, and James White.

At the Röntgen Society's next ordinary general meeting, on Thursday, January 7th, 1904, at 20, Hanover Square, a paper will be read by Dr. G. B. Batten on "The Revelations of Radium."

ART VELOX.—Messrs. J. J. Griffin and Sons, Ltd., of 20-26, Sardinia Street, London, W.C., announce the introduction of a new grade of Velox called Art Velox. The characteristics of the new paper are as follows:—It is coated with an emulsion which gives just the necessary amount of contrast for printing from average negatives, especially negatives of that density which are produced by the new developing machines or by time development. The surface is a mean between glossy and matt. The paper is slower than the other grades of Velox—hence considerably more latitude in exposure is secured. The prices are the same as Carbon Velox.

GLASGOW East-End Industrial Exhibition.—The fine art section of this exhibition, which was opened by Lord Balfour of Burleigh, on 9th December last, contains 331 frames in the Competitive Loan Photographic Section, and the Judges, Messrs. J. Craig Annan; Tom McEwan, R.S.W.; and James Patrick, who had at their disposal one gold, two silver, and an unlimited number of bronze medals and certificates, have now completed the judging. Owing to the number of good pictures of almost equal merit, it was thought that the difference between a gold and silver medal was too great a distinction to make, and the gold medal was therefore withheld, and an additional silver medal substituted for it. Three silver and two bronze medals and three certificates were awarded as follows, viz.: Silver medals, No. 46, "Evening on the Clyde," by W. S. McLachlan; No. 289, "Cantie wi' Little," by John Hepburn; No. 294, "Figure Study," by Alexander Allan. Bronze medals, No. 51, "My Little Dutch," by Arthur Marshall; No. 326, "A Pillar of the Church," also by Arthur Marshall; No. 226, "The Harbour," by T. Faston; No. 305, "From Choir to Transept," by W. G. Rowse; No. 386, "In the Height of the Storm," by F. J. Mortimer. Certificates, No. 207, "Evening, Loch Tay," by Thomas W. Robertson; No. 210, "A Calm Morning—Sunrise," by James Baillie; No. 245, "The Old Homestead," by John W. Downs. The Invitation Loan Collection contains 57 frames, which adds quite a finishing touch to the whole Photographic Section, and some idea of its merit can be formed when we know that it contains some examples of the work of such eminent men as Craig Annan, Fred. Hollyer, Arch. Cochrane, Harold Baker, F. Holland Day, F. H. Evans, James Patrick, William Crooke, Douglas English, Dr. C. F. Grindrod, David Blount, and many others. Taking it altogether, the Photographic Section must be considered a great success, and no one having the opportunity should miss paying it a visit. The Exhibition remains open until April.

Correspondence.

FIRE INSURANCE.

To the Editors.

Gentlemen,—The calendar contains a reminder that the premium for fire insurance is now due. May I, therefore, ask your powerful help to point out to policy-holders, and particularly to those insuring the contents of a private dwelling house, the very great difference between the insurance which they suppose themselves to have effected, and the actual contract which their policies represent? It will come as a great shock to many a householder when his eyes are opened to the pitfalls lurking beneath the ordinary domestic fire policy, and he realises what "a fool's paradise" he has secured, in exchange for his fire premium. By means of a "combine," known as the "Tariff Ring," the fire offices have not only hoodwinked the public, but have completely tied the hands of the Press, and have rendered it impossible for any report of fire insurance settlements to ever appear in any of the newspapers. So that, although the onus is upon the insured to thoroughly understand the full purport and effect of the very many and particularly obscure and complicated conditions of his policy, yet the ordinary means, and to many men practically the only means, of acquiring such information—the official reports of cases in the Press—are deliberately and purposely withheld by the fire offices, from reaching the public.

Now, a person estimates that the cost of replacement of his goods would, in the event of a total loss by fire, amount to a particular sum. He therefore elects to insure for this sum, and pays a premium accordingly. But although the office accepts this premium, and issues a policy for the sum named, there is no admission by the office, in terms, on the policy, that the insured's goods are of this value, or that his goods, or any part of them, exist at all. After a fire, when the things are destroyed, and the insured is asking for the loss to be made good, the office then, under the conditions of the policy, insists upon a thorough and exhaustive inquiry, and demands strict proof of every single item of the loss—not only as to its existence and value at the time of the fire but also as to when and where it was obtained and how much it cost.

The insured has to obtain, at his own expense, copies of the invoices and full details of the items from the books of account of the various persons from whom any of the articles claimed for were obtained, and is not entitled to be indemnified for any article whatever unless he not only specify it, but also substantiate and maintain the claim in respect of its value. The office deutes an assessor to ascertain the amount of the damage caused by the fire, and this amount, even in the case of a total loss, may, in the opinion of the office, be wholly out of proportion to the insured's estimate, and to the sum for which he insured. Indeed, it may not even reach a third of that sum. From these considerations it will readily be seen that after a fire, and particularly when a private dwelling house has been destroyed, there is every reasonable probability of a dispute arising between the insured and the offices—a dispute, of course, as to the amount of the loss. Indeed, the office has anticipated this, and accordingly has inserted in every policy a cunningly-devised clause, known as the arbitration clause, the effect of which is to deprive the insured of his ordinary right of action against the office in the public courts, and to compel all differences and matters in dispute to be referred to arbitration, which takes place in private. By means, therefore, of this compulsory arbitration clause, the insured forfeits his greatest protection—his right to sue the office, and seek justice in open court, upon any dispute arising under the policy, and the office is enabled, in the convenient obscurity which arbitration affords, to contest every single item of the claim, even down to articles of a few pence.

The arbitrator—a practising barrister—sits at the comfortable fee of 20 guineas a day, and naturally has no wish to shorten the inquiry;

the office continues in possession of the insured's premises and of the salvage, a proceeding that is certain to reflect adversely upon the insured, in proportion to the delay; the office interviews the persons with whom the insured has had business relations, and discusses in detail with them the item of the claim; the law costs mount up to a truly appalling sum; the goodwill of the insured's business (which, by the way, is not protected under his fire policy) is seriously menaced; and, indeed, every circumstance of the position becomes a factor in enabling the office to force a settlement. Under the sheltering power of this "law in the dark," the office bullies, insults, and torments the poor wretched insured to an extent that is positively scandalous, and fully conscious that no appeal is possible to the courts, and that no official report can reach the newspapers, the office raises the vilest possible insinuations, without daring to offer a single particle of evidence in support of them, or to attempt to justify them. Insurers, at the time of insuring, do not in the least appreciate the contract they are entering into, and it is not until a man's property has been destroyed by fire, and he is making a claim, that he realises how thoroughly and completely his policy conditions place him at the mercy of the office. He cannot sue the office for the amount he thinks he is entitled to be paid, and even should he succeed in proving before an arbitrator a far greater loss than the amount the office is willing to pay, the costs, the delay, the worry, and the anxiety entailed in doing so will more than counterbalance the advantage obtained. It needs no laboured argument to show that the way is thus carefully paved for the assessor, after a little judicious parleying, to drive a desperately hard bargain with his victim, with considerable advantage to the office, and a corresponding fee to the assessor.

These shameful compromises are now being advertised all over the country, under the catch-penny phrase of "prompt and liberal settlements"; but every insurer that hands over a premium to any tariff office on the faith of such advertisements will find that his policy, even though it be called an "unconditional fire (furniture) policy," contains the condition imposing arbitration, which, cruelly fulfilling its unholy function, extinguishes any chance of what the office pretends to promise to the insured—a "prompt and liberal settlement" of his loss. Let me, then, Mr. Editor, earnestly beg of your readers, for their own protection, not to accept any policy of fire insurance of which the arbitration clause is a condition. Upon whatever grounds of expediency its inclusion may be based, it is sufficiently significant that no straightforward explanation is forthcoming. With a view to more fully explain to householders their position under their policy, I issued a little pamphlet, based upon experience, dealing with "Some Difficulties of Fire Insurance." Through the courtesy of the Press, I have been enabled to distribute many thousands of copies, and unknown correspondents in all parts have thanked me most heartily for its publication, assuring me that its circulation is quite a public service. I have still some copies left, which can be had gratis, and possibly a perusal of this pamphlet, particularly just now, may be of very real interest to many of your readers.—I am, Sir, your obedient servant,

W. H. EADY, M.A.

Enfield, London, N., 21st December.

A WARNING.

To the Editors.

Gentlemen,—For the protection of your readers and the public generally in Great Britain, I desire to warn you against the practices of an individual styling himself U. Nehring, of 16, East Forty-Second Street, New York. Under pretence of manufacturing photographic goods, he has succeeded in swindling hundreds of unsuspecting people interested in photography in the United States. He operates in such a way as to just keep out of the clutches of the law.

I notice on his letter-heads, "Agencies in London and Berlin," which I presume he uses only as a further blind to enhance his own importance. His method of procedure is this: He sends out a mailing list of his own products, supplementing it with a sheet of bargains in second-hand Zeiss, Goerz, Voigtlaender, and other high-priced objectives. As far as any one has been able to find out, he has none of these lenses, and never had any of them, but he advises intending pur-

chasers to remit cash with order, so as to ensure first chance. To those who, like myself, have been caught with this improvised bait, he politely replies that the lens ordered has just been sold, but that he will send another just as good. An answer is sent that a substitute is not wanted, but to return the money at once if the lens ordered is not forthcoming. No response to this demand is made, but in course of a few weeks the party ordering, say, a high-class Zeiss lens has the privilege of paying expressage on a cheap-looking lens and mount marked "Nehring Anastigmat," which on trial proves worthless. It is returned at once, with demand for refunding of money, which, however, under one pretence or another, Nehring retains. Five of my friends in this city, as well as myself, have been thus swindled. Correspondence with the various magazines published in the United States also shows that they receive daily complaints of a similar nature regarding this man, and that he has never paid them for such advertising as he has hoodwinked them out of.

Fearing that he may be planning to transfer his field of activity to England (this country proving too hot for him), my object in writing you is to put you on your guard, in order that you may notify your readers.

Besides inferior lenses, he makes what he terms "ampliscopes" and "Nehring's Focussing Finder," both impossibilities, as well as other insignificant articles calculated to catch the eye of the public. They are not worth wasting time over. He keeps all remittances prepaid to him, without hope of recovery on the part of the victim.

I refer you, for confirmation of the above, to the Editors of the following magazines published in the United States, selected from widely separated localities, to show you that this man's manipulations are confined to no particular State or city:—"The Camera and Dark Room," New York; "The Camera," Philadelphia, Pa.; "The Photo-Beacon," Chicago, Ills.; "Camera-Craft," San Francisco, California.—

WALTER BRUCE,

PHOTOGRAPHIC WASHING.

To the Editors.

Gentlemen,—It is evident to everyone that the usual four hours' washing of photographs to eliminate the hypo is the cause of an enormous waste of water and time. Probably millions of gallons of water every week are wasted in this way. On this account I gave some attention to the matter, and have found a remedy which I desire to put before your readers. By my process five minutes is sufficient, instead of the four hours. Most chemists know that barium chloride has an exceedingly strong affinity for sulphur; it is even more energetic in this respect than lime. The formula of its action may be shown below:

This shows that by adding barium chloride to hyposulphite of soda both are broken up instantly. The barium unites with the sulphur and the soda with the chlorine, so that the products are barium sulphate and common salt. Now, barium sulphate, in this case, is a loose, very heavy, white (poisonous) powder, quite insoluble, easily rinsed off the photos, and the common salt remains in the solution. It has long been known that even common salt alone tends to quicken the process of hypo elimination. Then the process is quite simple. It is this: Make a 5 per cent. solution (exactitude is not necessary) of this barium chloride—which costs by retail about 1s. to 1s. 6d. per pound, or wholesale £4 to £5 sterling per ton, that is, about one halfpenny per pound. Put this solution in a dish ready for the dipping of all the photos.

When the photos have been developed and have been ten minutes in the hypo, rinse them for a minute in running water, and swab, if you will, on both sides with a cotton swab. Then dip for two minutes in the barium chloride, afterwards rinse again and swab the photo in

KODAK CO.'S LANTERN LIST.

Large diameter superior quality lens with stops, yellow cap, rack and pinion; duplex lamp, reversible carrier, rising front, fine adjustment focussing rack.

PRICE—

- No. 1, with $5\frac{1}{2}$ inch condenser, **£6 10s.**
 No. 2, with 6-inch condenser, **£8 10s.**
 No. 3, with $8\frac{1}{4}$ inch condenser, **£14.**

“ARTEX” CANTILEVER ENLARGER.

Finest quality enlarging lantern of Russian iron and brass-bound polished walnut, with every necessary movement.

THE “ORIEL” ENLARGER.

A new moderate-priced Enlarger, fitted with good condenser and lens, the latter fitted with iris diaphragm, rack and pinion, and yellow glass cap.

The body of this lantern is of Russian iron, with polished walnut front and base. It is also fitted with rising front, rack and pinion focussing and reversible negative holder.

The “Oriol” Enlarger can be had with either incandescent gas fittings or with a special oil lamp.

- | | |
|---|----------------|
| No. 1, with $5\frac{1}{2}$ inch condenser for $\frac{1}{4}$ -plate negative | £4 10 0 |
| No. 2, with $8\frac{1}{4}$ ” ” $\frac{1}{2}$ -plate ” | 7 15 0 |

“KONECTO” ENLARGER.

A new series of Enlarging Lanterns, specially arranged to use in connection with the photographer's own Kodak. The “Konecto” Enlarger consists of a Russian iron body with a walnut base and front. It is fitted with a good condenser, and can be had with either incandescent gas fittings or with a special oil lamp.

The front of the Enlarger is fitted with a carrier, on which the Kodak can be instantly attached or detached.

PHOTOGRAPHIC ENLARGERS PRINTERS IN ALL PROCESSES

BRIN'S OXYGEN.

For Limelight, Medical, Metallurgical, and other purposes.

OXYGEN of guaranteed purity supplied in Cylinders of the best British manufacture, and complying with all the established Trade and Railway Regulations.

THE Public are respectfully informed that all Cylinders which are filled by the undermentioned Companies (whether their own or their Customers') are labelled with their Trade Mark. This label guarantees the purity of the Gas, and is a further guarantee that the Cylinder has been tested and proved sound in every respect by the Company which has filled it. Customers are requested to see that the Cylinders supplied to them bear this label, which is also stamped with the date on which the Cylinder was filled. The Works of the Companies are open during business hours to Customers, who are at liberty to inspect the process of manufacturing Oxygen, and to witness their own Cylinders being tested and filled.

Price Lists of Gases, Cylinders, and all Accessories can be obtained from the Company's accredited Agents, or will be sent post free on application.

Addresses—

BRIN'S OXYGEN COMPANY, Limited, 34, Victoria Street, WESTMINSTER, S.W.
Works—69, Horseferry Road, WESTMINSTER, S.W.
MANCHESTER OXYGEN COMPANY, Limited, Great Marlborough Street, MANCHESTER.
BIRMINGHAM OXYGEN COMPANY, Limited, Saltley Works, BIRMINGHAM.

the running water. That is all. Five minutes is sufficient, instead of the four hours. I find, also, that the whites of the photos are improved by this process.

Your readers will no doubt vote to me a monument for this invention; but also, I think, I have a fair claim to the gratitude of water-supply companies.—I am, yours, etc.,

JOHN NOTON.

Southport, December 29th, 1903.

THE ILLINGWORTH COMPETITIONS.

To the Editors.

Gentlemen,—We have pleasure in telling you that in our recent Bromide "Sample" Competition, wherein we sent gratis to every applicant three sample pieces of our new bromide paper, we have had a magnificent response, over 600 entries having been received. The quality of the prints being so good, we gave five extra prizes of £1 each. The winning print was sent in by Mr. Herbert Birstow, 5, Hyde Park Gardens, Halifax, and the five extra were won as follows: Mrs. Manson, Bury St. Edmunds; Miss Constance Ellis, Shalford, Surrey; Mr. John Malcomson, Belfast; Mr. John Wickens, Upper Bangor, N. Wales; Mr. Nicholas E. Smirnoff, London, W.—With compliments, we are, yours faithfully,

THOMAS ILLINGWORTH AND CO., LTD.

Willesden Junction, London, N.W.,
December 29th, 1903.

FILM TROUBLES.

To the Editors.

Gentlemen,—I am writing to you to inquire whether you can inform me as to the cause of the markings on the enclosed film.

It is rather curious, but a number of films which I developed before made a trip of 300 miles up the river were all right, but in this No. 2 size and also in a No. 5, but both, on returning and on being developed, showed the same markings; plates, although no particular care was taken in packing, were not affected.

The films were packed in cotton-wool and in tin boxes, and adhesive plaster put round to keep them as airtight as possible. If you could explain I would be extremely grateful.

I have developed all with pyro-soda developer. The only thing is, that the sodium sulphite has effervesced; but this was the case before started from Sesheke, and when I developed the first lot. None of the films were over-date when developed. The water was also cool and good Zambesi water.

I have developed at different times a large number of spoils, but have never found quite the same markings.

The enclosed photo is not of the Victoria Falls, but of the Onya Falls, Siomo, which is about 300 miles higher up the river; they are very little known, and I suppose I am the first one who has ever photographed them from one end to the other. The fall of water is about 100ft., and the Zambesi at this point is about a mile wide. The falls are charming although not nearly as grand as the Victoria Falls. I went up from Kasangula to Sesheke, and from here to Lialui by the native dug-out. They are rummy things to travel in, and a bit shaky, and are generally paddled by from three to six niggers, who stand up in the boat and paddle. I only got upset once, in some rapids but got a dose of fever from it, as I was upset just before sun-down, and had to sleep in wet blankets.

Sport is very good; you get bick buck, Quagga, and I saw elephant too; but of course I had just expended my last cartridge at the time. I also shot "hippo" as well.

I could write you a long letter on my experiences, but am afraid you are far too busy to give attention to the trials and tribulations of one who is unknown to you.

I may mention in conclusion that I have been a subscriber to your "Journal" for several years now, and I have read it in a good many

curious places. I read the last one I had pretty thoroughly as I came down from Lualaba, as I was entirely by myself, with the exception of about fifty porters; even the "ads." were read and re-read.

I suppose when you receive this the festive season will be upon us. I hope I shall not be 500 miles from a railway and liquid refreshment as I was not long since.

With kindest regards and every good wish for a happy Christmas and a prosperous New Year.—Believe me, yours truly,

PERCY M. CLARK.

Sesheke, Zambesi River, Barotseland, Africa.

November 15th, 1903.

P.S.—If you by any chance have a 1904 Almanac left, would you kindly send it?

[The markings to which our correspondent refers are of a reticular character. In early gelatine days we traced the effect to the use of an overheated developing solution.—Eds., B.J.P.]

MR. DRINKWATER BUTT, F.R.P.S., of Gower Street and Kensington, has just completed designs and accepted the tender of Mr. A. Cliff, of Evesham, for additions and alterations at The Den, Crophorne, Worcestershire, the residence of Mr. A. H. Avery, a partner in the well-known firm of scale-makers of Birmingham. This picturesque country house, overlooking the valley of the Avon, was originally a group of cottages of the half-timber period characteristic of the neighbourhood, and was converted into a single house by the late Sir Lawson Tait, the eminent surgeon. Since the property came into the hands of Mr. Avery it has been further improved under the direction of Mr. Edwin Lutyens and Mr. Drinkwater Butt, the former designing the quaint sunk garden, and the latter restoring the old-style leading of the windows, and being now responsible for the additions, new gables, etc. Great care has been taken in the preservation of the old work, and in making the new to thoroughly harmonise with it.—"The Building News."

THE Egyptian Hall, the approaching demolition of which was announced last week by Mr. Maskelyne, has been more or less devoted to picture exhibitions since the dispersal of the Bullock Natural History Museum. It was in 1812 that the Egyptian Hall was built with its present frontage by Mr. Bullock, says "The Morning Post," in what was then regarded as "a style of magnificence which has added an ornament to the Metropolis," but in 1819 the Bullock collection was sold by auction, and two years afterwards the proprietor let one of his galleries to the Old Water-Colour Society, whose exhibition was held in the room thus hired (the "Roman" Gallery) in 1821 and 1822. Haydon had already in 1820 showed his "Jerusalem" to crowds of sightseers at the Egyptian Hall, where a quarter of a century later the despairing painter exhibited his last efforts in the shape of some large subject pictures. The exhibition of 1846 was an absolute failure. It resulted in a loss to the artist of more than £100, while Tom Thumb, who was shown at the same time in the Egyptian Hall, attracted thousands of visitors. This was the last straw, and Haydon committed suicide on the 20th of June. Six years later, in 1852, the Dudley collection of Old Masters was shown in the room that has since been known as the Dudley Gallery, and in 1858 the second exhibition of the newly-formed Society of Lady Artists was held in another room of the Egyptian Hall. In 1865 a body of artists began the exhibitions that were commonly called the "Dudley," after the room in which they were held. To the Dudley exhibitions many of our strongest water-colours painters contributed until the reorganisation of the Society in 1883. It was, too, at the Dudley in 1881 that the Queen, as Princess of Wales, made her first appearance as an exhibitor at a public gallery. Some years later a well-known critic, Mr. Harry Quilter, showed, amid luxurious surroundings, the results of his labours in various fields of art, and the Dudley Gallery Art Society has held regular exhibitions at the Egyptian Hall since the old "Dudley" was dissolved in 1883. The disappearance of a building with such curiously varied and interesting artistic associations will be regretted by all painters, but by none so keenly as those who are connected with the New English Art Club, which has in the Dudley Gallery a room exactly fitted for its exhibitions, both in size and locality.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- W. J. Usherwood, Station Road, Penrith. *Photograph of railway collision at Penrith Station.*
- J. C. Brown, The Studio, High Street, Annan, N.B. *Two photographs of fishing fleet at Annan.*
- A. A. Grigor, Johannesburg, Transvaal, S. Africa. *Photograph of Mrs. Ians, the N.C.O.'s of the Grigor-Ians' family and their decorations.*
- T. Mason, 164, Market Street, Crewe. *Photograph of Crewe Volunteers and Reservists' Memorial Monument.*
- E. G. Brewis, 8, New Bridge Street, Newcastle-on-Tyne. *Eight photographs of Miss B. J. Lindsay.*

PAINTING REGISTERED:—

- W. G. Wise, Camp Studio, Bulford Camp, near Salisbury. *Painting consisting of a crown, gun, scrolls, two Latin inscriptions, four flags, and circle of rose, shamrock, and thistle.*
- C. M. PARROTT.—1. Obtainable, we believe, of Messrs. Percy Lund, Humphries, and Co., Bradford. 2. Two shillings and three pence per dozen.

TOYM.—If the agreement was for a specific use (say one issue of a paper), and the reproduction was employed for another purpose, we believe you could recover.

LANTERN PLATES.—CYANTYPE.—"E. Y. E. N." says: "Can you kindly inform me (1) Where chloro-bromo plates more rapid than 'Alpha' plates, and as transparent, are to be obtained? (2) How long will the mixed solutions for cyanotype (viz., ammonio-citrate and ferricyanide) keep? Will they keep two hours or more?" In reply: (1) Try the "Special" lantern plates of the same makers as the "Alpha." (2) Yes.

POSTCARD PHOTOGRAPHY.—"POSTCARD" writes: "Will you please tell me if you consider enclosed postcard mask worth patenting and putting on the market? It is simple, and light-tight for daylight work, even when card projects from printing-frame, and for gas-light work the card can be held in contact with negative for printing without the use of printing frame, thus saving a lot of time now wasted with ordinary masks and frames." In reply: We do not think our correspondent's idea worth a patent. The best way, however, to test its commercial value is to obtain provisional protection for it, and then submit it to some house which makes a speciality of post-card photography.

CLEANING DAGUERRETYPE.—"LARGO" says: "I should esteem it a favour if you could let me know the best method of cleaning a Daguerreotype on copper. It has become stained and discoloured." In reply: The tarnish may be removed with a solution of cyanide of potassium. Rinse the Daguerreotype under the tap until the water flows freely; then pour on and off, say, a 10-grain solution of cyanide of potassium until the tarnish is removed, and then well wash with distilled water. Unless you are familiar with the Daguerreotype process, and we assume you are not, we should advise you to experiment with one or two valuable pictures before attempting to deal with a valuable one. Or, better still, entrust the work to an expert in the process. Bear in mind that the image in a Daguerreotype is a very delicate one, and easily irreparably ruined.

LENS FOR HAND CAMERA.—"FOCAL LENGTH" asks: "Will you kindly reply to the following in next week's paper? No. 1. For a

quarter-plate and five by four hand camera, what would be the best focal length of lens, respectively, to buy, in order to secure good perspective? No. 2. I am quite in the dark about this matter of perspective, for on a quarter-plate, with a lens of 5½ in. focus, I get a negative which I am told is worth enlarging, the subject being a beach scene. Again, on the same size plate (quarter-plate), with a 5½ in. focus, I secure a harbour scene, with a vessel as the principal object, but am told that there is exaggerated perspective, owing to a lens of too short focus being used. What I do not understand is that with the lens a quarter of an inch longer focus, false perspective should be attributed to my effort, when nothing is said about such a defect in the beach scene, with a lens of shorter focus is used. Can you kindly put me on the right track by telling me what focal length of lens to use on a quarter-plate to avoid this exaggerated perspective, whether I attempt an ordinary beach scene or a harbour scene with a vessel in the foreground? No. 3. Recently I saw a print for criticism, which had been taken on a quarter-plate with a 5½ in. focus lens, and thinking that the focus of a lens for a quarter-plate ought not, for correct perspective, to have been less than about 6½ in. focus (i.e., one and a half times the longest side of the plate). I asked that if I wished to enlarge this print, how much I ought to cut away from the foreground in order to make up for the deficiency of a too short focus lens, and to procure good perspective in enlargement, the reply being that no further help would be given to me unless I stated the size to which I intended to enlarge. Will you kindly explain, as I am here totally in the dark, and if possible tell me to what size to enlarge to secure a more agreeable perspective?" In reply: 1. For a quarter-plate, lenses of about 5½ in. are what are generally employed, and for the five by four sizes those of about 6½ in. 2. In neither case is the perspective false or exaggerated. Pictures are taken with short focus lenses, the perspective may be violent and unpleasing, but it is still true. 3. Simply away sufficient of the foreground, if there be too much, to make a pleasing picture. It is simply a matter of taste and judgment. There are no set rules in the matter.

HOLMFIRTH and District Photographic Society.—An Exhibition of Photographic Work will be held in the Technical Institute, Holmfirth, on Friday and Saturday, January 8th and 9th, 1904. The judges will be Messrs. Godfrey Bingley and Gilbert Foster, R.B.A. Admission—Season ticket, 1s.; after 6 p.m. on Friday, 6d.; Saturday, 3d.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—Members' Competition. The following are the results:—Silver medal, presented by Mr. Calder Marshall, for the best print illustrating the subject "Solitude," awarded to Mr. C. H. Oakden, F.R.P.S. Bronze medal, presented to Mr. C. Churchill, F.R.P.S., for members who had not previously gained an award, won by Mr. G. W. Clarke. "Excursion" Silver medal, offered by Mr. J. T. French, withheld, there being sufficient competitors: 1st, H. C. Beckett; 2nd, E. W. Taylor. Judges were Messrs. Selfe and Steen, of the Hackney Photographic Society.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Setting of Gelatine. Dr. Paul von Schroeder is quoted in a recent number of "Nature" as pointing out that gelatine solutions undergo two types of change, a non-reversible hydrolysis by which the setting power of the solution is permanently impaired, and a reversible change as the result of which the jelly melts when heated and slowly solidifies when cooled. The setting power of a solution is accurately indicated by its viscosity. If after rapidly cooling from 100 deg. the viscosity is measured at 25 deg., a low value is obtained which gradually increases until, if the decomposition of the gelatine has not proceeded too far, it culminates in the setting of the whole mass. By measuring the increment of viscosity during one hour it is possible to predict whether the solution will set in the course of the next twenty-four hours. The reverse process by which the gelatine swells and then dissolves in water presents similar points of interest. Gelatine saturated with water has a higher vapour-pressure than water itself, and loses weight in a saturated atmosphere.

A New Work on Optics. Eleven years have passed since Dr. Czapski's work on the "Theory of Optical Instruments, according to Abbe," was published. Three years ago the author was approached, and asked to revise the work, but he soon realised that the pressure of his

duties rendered the task an impossible one. To these circumstances we owe the conception of the present work, the first volume of which has just been published by Julius Springer, of Berlin, under the title: "Die Bilderzeugung in Optischen Instrumenten vom Standpunkte der Geometrischer Optik" ("Formation of the Image in Optical Instruments, from the Point of View of Geometrical Optics"). The authorship is a combined one, in which the scientific staff of the Carl Zeiss Optical Works have taken part, the writers being Drs. P. Culmann, S. Czapski, A. Koenig, F. Löwe, M. von Rohr, H. Siedentopf, and E. Wandersleb. The onerous duty of editing the volume was undertaken by Dr. M. von Rohr. Some idea of the comprehensiveness of the book may be formed from the fact that it is an exposition of the writings of the more important authors upon optics, whose theories in some cases have been extended. The chapter on Abbe's geometrical theory of optical delineation may be looked upon as authoritative. Very important modifications of Dr. Czapski's treatise will be found in Chapters 5, 6, and 9, written by Dr. Koenig and Dr. Moritz von Rohr. We can only give in these few lines an indication of the scope of this work, but we look upon it as one of exceptional value to the theoretical optician.

Jan Szczepanik. We have heard much in this country of this extraordinary inventive genius, whose work, measured by the amount of printers' ink spent upon it, is destined to be of great importance to mankind. "Photographische Industrie," however, publishes an appreciation of his work, which differs materially from the popular idea, so carefully nursed by the daily Press. In 1898 the Telectroscope was announced. This instrument was to bring within our sight objects at a distance by electrical means. It was to have been exhibited at the Paris Exposition in 1900, but instead, only a series of drawings illustrating the proposed solution of the problem were forthcoming. Next we were startled by the invention of a method by which photographs could be reproduced in textile fabrics, without the intervention of the designer; but an advertisement in the "Wiener Zeitung" supplies a significant comment upon the practical value of the process, the whole plant of the "Jan Szczepanik, Société des Inventions" being offered for sale at public auction by the judicial authorities. Recently an equally remarkable invention was produced by this prolific brain. The problem of colour photography was solved, and a patent obtained for a process in which the three films of stained gelatine were isolated by intermediate films of collodion. Dr. Neuhauss, of Berlin, experimented with the process, condemned it as quite impracticable, and pronounced it not worth printers' ink. Its only redeeming feature was

the money it had brought to the Patent Office in the shape of fees. We look forward with interest to the next great invention of this remarkable man.

The Weather in 1903.

No one requires reminding that the year just past was an exceedingly wet one, and by no means propitious to outdoor photography. Now that the year is finished it is interesting to see from the statistics that have been issued what the weather really was. The return for London (Brixton) of the rainfall for the year was 37.95 inches, and is the largest recorded for the last sixty years; and it is nearly double what we had in 1902, when it was only 19.28 inches. It is curious to note that the wettest months were the three summer ones, June, July, and August, the aggregate excess for these three months being no less than 9.47 inches above the average. It is also curious to note that February ("fill dyke") was the driest month of the year, and that the year's rainfall at Greenwich was 2.37 inches less than it was at Brixton. Yarmouth, curiously enough, had less rain than usual last year; the total fall there was but 24.8 inches, while the average is 26.4 inches. Many have thought that last year was, with so much rain, a very cold one, but the returns show that it was not, for the temperature was 0.3deg. in excess of the average for the last sixty years, and is 1deg. warmer than 1902. These are the Greenwich returns, and they are pretty much in accord with those of Brixton as regards the temperature. The warmest months of the year were July and August; but they were both below the average. The months with the temperature above the average were January, February, March, May, October, and November, and the greatest excess was in February, which had 5.5deg. In the whole year there were only eight days with the thermometer over 80deg. With regard to sunlight, always an interesting subject to photographers, it appears that June and August both had 188 hours of sunshine, and there were upwards of 180 hours in May and July. It appears there were at Greenwich in all 180 hours more sunshine than usual. It, therefore, seems, contrary to what many outdoor photographers may have surmised, that they have not much to complain of regarding light, wet though the year has been, seeing that we had 180 hours bright sunshine in excess of the average.

Snow Pictures.

Up to the present photographers in the home district have had no opportunity of obtaining pictures of snow or wintry subjects, as in this uncertain climate of ours it is impossible to even conjecture when they will have, or whether they will have at all, this winter. There is no doubt whatever that if the chance arises it will be quickly availed of by many. Now the taking of photographs of snow pictures, given the snow, is by no means difficult, and moreover, subjects that would otherwise be uninteresting often become excellent ones when clad with a covering of snow. Although snow subjects are not difficult to deal with, amateur results, as a rule, are far from being satisfactory. This is possibly due to the fact that they so seldom have the opportunity of trying their hands in this direction. Many who have only taken up photography during the last year, of course, have not yet tried their "prentice" hand at the work. One of the great faults with snow pictures is that there are no half-tones, or delicate gradations, in the snow itself. It is usually a bald white mass, without detail. This, in the majority of cases, arises from the development being carried too far, so that the finer gradations become buried. Some, when they make their first essay in de-

veloping a picture of a snow scene, may be inclined to take the sky as a guide as to the density required. But this should not be done; the snow itself should be the criterion. Some years ago, we remember there was a little discussion as to whether in a snow picture the sky or the snow should be the lighter of the two, and their opinions seemed to differ. But there is no question that pictorially, the snow should be the whiter and the more brilliant. We have now hanging before us an excellent reproduction of a drawing of Rowbottom's, entitled "Winter." In this the snow where the light strikes it is a brilliant white, while in the other portions of the snow the white is slightly subdued, being a little more grey. The sky in the horizon is a tolerable dark grey, and at the upper portion a lighter grey, but nothing approaching that of the snow, except towards the shadows. In taking pictures of snow subjects, under-exposure should be avoided, and in the development the high lights on the snow should be taken as the guide to density, and nothing else. The sky may then appear somewhat thin, but then it should print darker than the snow itself. These little hints may just now be of service to some amateurs who have not yet attempted the photographing of winter scenes, for it may happen that their first attempt may be their last for many months, as, with this fickle climate of ours, we may have a heavy fall of snow one day, and it may be all melted the next; and perhaps we may have no more until next winter. Therefore the chance should not be lost through failure in the manipulations.

Sulphocyanides of Silver and Potassium.

The downfall of the old gold toning and fixing both was assured by the researches of Messrs. Davanne and Girard, who showed, half a century ago almost, how *inter alia* two compounds of silver with what was then termed hyposulphite of soda existed, one soluble and stable, and the other extremely unstable. This latter was formed by the action of an insufficient amount of the hypo upon the silver chloride, and was almost a normal condition of the old toning and fixing bath saturated with silver in a minimum amount of hypo. The state of affairs was well indicated by the colour of the prints, rich purples, but very yellow whites. All that colour scale is altered now; we get any range of shades from sepia to almost black, and the whites, instead of the dingy yellow, are pure as the paper itself. At the same time in view of the immense popularity of the sulphocyanide toning solution, and the millions of prints produced by its aid now spread over the world it is worth a moment's thought to consider whether there may be any parallel between the two. Formerly we had a maximum of silver and a minimum of solvent—result: fading. Now we have a maximum of silver and a minimum of a still weaker solvent. Result: query. But, after all, the cases are not quite on all fours; for in the modern toning, although, at first, the print is subjected to conditions analogous to those of the dangerous old bath, they very soon are treated (or should be) to a bath capable of dissolving away at a rapid rate all the silver chloride present, and very much more if it were there to be acted on. Some experiments recently made by Mr. Harry W. Foote, according to the American "Chemical Journal," allow some little trepidation in this respect, for he finds thiocyanide compounds alarmingly similar to the thiosulphite. He used double thiocyanates of silver and potassium, and, on the authority of the makers, Messrs. Wells and Merriman, he gives three distinct compounds as being preparable, containing respectively one, two and three equivalents of thiocyanide, and it is to be remarked that the salt with one equivalent is unstable and at ordinary temperatures

readily dissociates, but not with the formation of those treacherous sulpho acids which accompany the decomposition of hypo in contact with silver chloride.

* * *

The Roller Squeegee. A more useful piece of apparatus than the roller squeegee it would be hard to find, for it can be turned to so many purposes, both inside and outside the photographic work-room. It will do anything from the rubbing smooth a refractory print, to giving a smooth layer of ink to a collotype plate. But until we read an advertisement just now current in one of the non-photographic journals, we had no idea that the little roller could be employed in ways quite foreign to "the daily round, the common task." Perhaps we should not have realised the full extent of these new applications of the giddy roller, had the advertisement in question not been endowed with a picture of a young lady who is shown busily squeegeeing her face with the implement in question. It was this picture that led us on, like her mother, Eve, to inquire with the curiosity peculiar to man, into the inner meaning of this thing. In other words, we read the advertisement, and this is what we learnt about it. The roller in question is described as a new beautifier, which is warranted to produce a perfect complexion, removing wrinkles, crows'-feet, and all facial blemishes; besides this it will develop, or reduce as desired. These facts are not given on the mere word of the advertiser, but are vouched for by two American papers, and we therefore need not stop to inquire whether they are true or not. And we may at once explain that the development and reduction here mentioned have nothing to do with the same terms used in their photographic sense. It is a development or reduction of different parts of the body which are indicated. It is a cure for want of plumpness, or too much rotundity, as the case may be, and it must be confessed that this roller is gifted with extraordinary powers if it can make at will either a hill or valley on the human frame. Then we read that it is "an electric roller in the strictest sense," whatever that may mean; but as it has been designed "by a physician and electrician known throughout Europe," our confidence is restored, and we know that the word "electric" is not used as it is by some ignorant advertisers merely as a catch-penny device. To advertisers of that stamp the word "electric" is even more blessed than "mesopotamia," and they apply it to anything from a pill to a hairbrush. The electric roller requires "no charging" (it is the buyers of it who are charged), and it will last, like radium, for ever. "No shock, sting, or burn, as in the old batteries, but pleasant and soothing in its action. Always ready for use on all parts of the body for all diseases." This is, indeed, a great discovery, and one specially valuable to a photographer, for he has the apparatus at hand. No more doctors' bills. If disease attacks any parts of the body, he has merely to give it a rub with the roller squeegee and he will be cured. Possibly there may be a bit of magnetised steel hidden in this particular electric roller "to save its face"—to use a provincialism—and it would be advisable to purchase one in order to see whether that is the case; but, on the whole, we believe that the photographic implement as commonly used would be quite as efficacious as the "electric" one.

Speaking Likenesses.

M. Bertillon, whose name is so widely known as Chief of the Anthropometrical Department of the Prefecture of Police in Paris, has recently much extended the use of photography for the identification of criminals and undesirables. He is aware

that a single photograph of a man is likely to mislead the police, and to very often cause the arrest of the wrong person, and, as a matter of fact, the blunders of this description have run up to as much as sixty per cent. In financial affairs this is generally looked upon as a very high rate of interest, and it is certainly rather too much for justice to countenance when applied to the identification of innocent persons. A new system which is termed "portraits partes" has therefore been introduced, and it is found so successful in practice that the failures have been reduced to one per cent. The "portrait parte" does not depend upon one picture, but upon several, the object being to analyse, as it were, each face with a view to making a study of the different features. The police are being instructed in this new system, and although at the outset they did not take very kindly to it, they are now quite interested in the matter, and have taken it up with the greatest enthusiasm. Some novelists are very prone to give elaborate details of the eyes of their heroes and heroines, while the mouth and the nose are always of secondary importance. But, according to M. Bertillon, the ear is the feature which possesses the greatest variety of shapes, and therefore in the "portrait parte" the ear stands first in importance as a means of identification. There are fifteen other details of the head and face to which the police have to pay attention. Indeed, the myrmidons of the law have to understand the "points" of a human being, just as a fancier understands the various "points" of a dog. The need of identification is much greater in the Paris police offices than in London, for the French officers have greater powers than our police have over here. In addition to the vulgar criminal, there are no fewer than 1,500 persons to whom France is forbidden. What a blessed thing it would be for Londoners did such a law prevail here, for there are many undesirables who "never would be missed"; but we cherish not only our own scum, but the unsavoury skimmings from all the other European capitals, including, of course, the 1,500 for whom France is too hot. Then besides these the French police have to keep a good look-out for a few hundred criminals who have escaped from the penal settlements in Guiana and New Caledonia. These have all had their photographs taken, at the expense of the State, in several positions, full face and side face, so that the shape of the nose, mouth, ears, etc., can be duly noted and measured, each picture being one-tenth the size of the original. In one month, by aid of these portraits, twenty-five persons have been arrested, and in each case the right man has been taken. Truly "the way of the transgressor is hard," but it has become a good deal harder since M. Bertillon made such extended use of the photographic camera.

The London and Provincial Photographic Association.—The hon. secretary has issued the following notice to members:—In handing you herewith a copy of the programme for the ensuing quarter, I beg to draw your attention to the papers to be read before the Association. I trust you will, by frequent attendance, endorse my efforts to make the L. and P. a centre of photographic interest and information: The papers will be of wide interest and are by competent exponents, and it now remains for members to show their appreciation of the kindness of the lecturers, by giving them a "full house" and hearty reception. It places myself and your officers in a very awkward position when we can only offer a small audience as the sole return for the time and trouble taken. The annual supper will take place on February 18th, and I shall be glad to forward tickets at 3s. each. The chair will be taken by Mr. E. J. Wall. The affiliation competition pictures and slides will be judged on January 14th by Messrs. Thomas, Salmon, and Mackie, and I shall be pleased to furnish further particulars.

WINTER TROUBLES AND WINTER PRECAUTIONS.

By the time this issue of the JOURNAL is in the hands of readers we shall be well in the year 1904, and up to the present—that is, up to the time of writing—we have had no severe wintry weather. Those who have been looking forward to a time when they could obtain snow and frost pictures are still awaiting the opportunity. Still there is ample time for us to have what is sometimes described as a “good old-fashioned winter.” Now a good old-fashioned winter brings with it considerable inconvenience, and to none, perhaps, greater than to photographers, particularly if they are attended with a frozen water supply, for example.

Although up to the present there has been no really inclement weather yet, it has been cold enough to occasion inconvenience, and sometimes trouble, the cause of which has been unsuspected by some whose practical acquaintance with photography is somewhat limited. Indeed, we know of more than one instance of trouble, due entirely to depressed temperature, the cause of which was actually unrealised by the photographers, yet they were professionals, though, we may add, not with a very extended experience in the business. The trouble here referred to was at first attributed to the quality of the plates; they were charged with being slow, though they were of a very quick brand; also that they would not yield sufficient printing density. In each case the difficulty, when the cause was explained, was got over by warming the developing solutions and the dishes to about 56deg. or 70deg.F., as well as the dark-room itself. It is commonly recommended at this season to warm the developer up to this temperature, but a little consideration will show that the advantage gained is quickly discounted if the temperature of the room itself is not much above 40deg., and this is frequently the case with some dark-rooms. Under such conditions the solutions rapidly cool, and the advantages, gained at first, become next to nil before the development is complete, if it is at all long, and in the case of under-exposure it may necessarily be so.

When there are no other means of heating the room, a paraffin stove becomes very convenient. One with a four, or four-and-a-half-inch wick will keep a good-sized dark-room at a genial temperature, and the solutions in good working order during the daytime, and a common paraffin lamp, with an inch wick, will do the same during the night with the door shut, notwithstanding that the outside temperature may be at the freezing point. Objection is sometimes raised to paraffin stoves on account of smell. This objection becomes groundless, as it does with oil lanterns, if the wicks be kept nicely trimmed and the outsides of the reservoirs perfectly clean. Although the fumes from a neglected oil-stove are unpleasant to smell, they, unlike those from coke or gas, have no injurious action on photographic operations.

Depression of temperature retards chemical action, and has a marvellous effect on the fixation of both negatives and prints. They fix much slower than when the solutions are warmer, but in the case of negatives the effect can be seen, and if care be taken that the plate remains in the fixing-bath for double the time it took to remove the bromide of silver, not much trouble will be met with as regards that operation. But if not, and the negative has to be intensified, stains may well be anticipated. In the case of paper prints, there is no such guide as to complete fixation, and the conversion of the hypo-silver salts into the freely soluble condition, and, as a result, yellow stains frequently make their appearance when the prints are finished, owing to their being insufficiently fixed. At

this season of the year, if the fixing-bath is anything under 30deg., and the room is cold, at least double the usual time in the solution should be allowed to ensure that the prints are perfectly fixed, and the hypo-salts of silver brought into the freely soluble state, necessary for their entire removal. Even when this is done there comes the question of washing.

When the water is very cold it has not the same solvent action on the hypo in the films, whether plates or paper; hence, unless the washing waters are warmed, a longer time should be given to the washing; but in the majority of cases this is not done. Indeed, when the operation is entrusted solely to inexperienced lads and girls it is often curtailed on account of the unpleasantness of having to be continually dabbling in abnormally cold water. Where the albumen, or the collodio-chloride, processes are employed this is not so likely to be the case as with them. Warmer or even hot water may be employed for the washing. This treatment the majority of gelatine papers will not stand.

Having alluded to some of the troubles that winter cold may bring about, there is perhaps a still greater one that may beset the professional worker—namely, a frozen water supply. This, in the greater number of cases, may be avoided were a few timely precautions taken; yet they are too often neglected until too late. There is now sold by most of the large ironmongers a thick felt, made specially for binding round exposed water-pipes. This felt is an excellent non-conductor of heat, and affords a good protection to the pipes. In place of that the hay bands, with which trusses of hay are bound together, if wound round the pipes answers well. When the service pipe from the street main is laid near the surface of the ground, as is too often the case, six inches of stable manure laid on the ground above it will prevent the frost from reaching the pipe. Another good way of preventing the water from freezing in the pipes is to leave the taps continually dribbling. This, of course, the water companies would object to if they knew of it; but they need not be consulted on the subject. If the water is paid for by meter they raise no objection, of course, as the slight extra cost to the consumer is sometimes amply compensated for in the avoidance of a frozen-up supply, and, perhaps, burst pipes. If perchance for want of due precaution being taken, the pipes get frozen, they should, without delay, be examined from end to end to see if there are any bursts. If there are, they will be seen as enlargements of the pipe at those places, and the services of a plumber should be sought at once to do the necessary repairs. If this be neglected, it may result in the flooding of the place when a thaw sets in, and possibly much damage being done.

By the death of Mr. Mason Jackson, which occurred in London on December 29th, in his eighty-fifth year, journalism has lost one of its most respected veterans. Mr. Jackson was for thirty-five years the art editor of the “Illustrated London News,” taking that position after the death of Mr. Herbert Ingram, M.P. In this capacity Mr. Jackson wielded considerable influence in the development of illustrated journalism, and his book on the progress of this section of newspaper work is a standard history which no writer on the advance of the Press can neglect. Mr. Jackson came from the county of Thomas Bewick, and like him was an engraver. His first work for the Press was done for the “Morning Chronicle,” in the absence of his brother, Mr. John Jackson, a well-known wood engraver. Joining the staff of the “Illustrated London News,” he had much to do with the enterprising record of historic events which that pioneer of illustrated journals contained during the Victorian era. Mr. Jackson was well known to most black-and-white artists, and he has left the memory of a genial and upright man.—“The Times.”

THE MICRO-PLANAR LENS COMPARED WITH A FIRST-CLASS LOW-POWER MICRO-OBJECTIVE.

AN article on "The Micro-Planar Lens," which appeared in the JOURNAL of October 30th, 1903, has greatly interested me, in view of the fact that I have had considerable experience in the use of one of these lenses (a 75 mm. by Zeiss) during the past year, the results of which do not lead me to the conclusions reached by its writer, Mr. J. I. Pigg. Believing that the subject, as viewed from another standpoint, may prove interesting, I venture to record here my own observations and conclusions.

The construction and appearance of the micro-planars are so lucidly described by Mr. Pigg as to require no further remarks. He is mistaken, however, when he gives the 2in. as the lowest power of this form of lens. Zeiss lists five sizes—20, 35, 50, 75, and 100 mm., or $\frac{3}{4}$ in., 1 $\frac{1}{4}$ in., 2in., 3in., and 4in. equivalent foci respectively. His experience was with the 35 mm., or 1 $\frac{1}{4}$ in. size, my own, as stated, with the 75 mm., or 3in.

The micro-planars are, in fact, photographic lenses of very short foci, specially designed for moderate enlargements of both opaque and transparent subjects, notably the three larger sizes, 50 mm., 75 mm., and 100 mm., which can be used only on a microscope with very wide body, as furnished in the Zeiss stand, intended for this work, or by attachment directly to the camera. The amplifications obtainable with these are quite low, even with long bellows cameras rarely exceeding 10 diameters—photo-macrographs, in fact. The two smaller sizes—20 mm. and 35 mm.—are fitted with the Society screw, adapting them to any microscope, and with these photo-micrographs of moderate magnifications can be made without excessive length of bellows in the camera. But since none of them can be used with an ocular their range of amplification is quite limited.

The use of photographic lenses for photo-macrography, or photo-micrography, is no new thing, however. I have so employed them for more than a dozen years with excellent results. Beck's rapid rectilinears of 5in. and 7in. foci, their wide angle of 3 $\frac{1}{2}$ in., and Ross's concentric 4in. have constituted my battery for amplifications up to 8 diameters. Samples of their work may be seen in my little book, "The A B C of Photo-micrography."

In comparing the performances of an ordinary achromat and micro-planar of same foci, it seems to me that both should be used with full openings, as the former must be, necessarily. But Mr. Pigg finds that with objects requiring "exceptional depth of definition" the micro-planar may be stopped down to F. 16, which, of course, will greatly increase its performance in that direction, to the disadvantage of the achromat. My own experience with these two lenses seems to show that, with the micro-planar, used at its full opening upon objects having several planes of surface requiring "exceptional depth of definition," there is but little difference in their performances, the achromat having perhaps a slight advantage over the other. Stopped down to F. 16, the micro-planar is at its best for this sort of work, and possibly better than its rivals.

But—there are, of course, lenses and lenses, notably among the very low powers. My own 3in. is by Beck, as are equally fine 1 $\frac{1}{4}$ in., 2in., and 4in., which I am the happy possessor of. I do not believe a finer 3in. exists, although it was made more than twenty-five years ago, and has been in steady use all that time. It is corrected for photography by Wenham's method—the insertion of a double convex lens of some 6in. focus in the extreme rear of its mounting. The full opening is slightly less than that of the micro-planar, but the numerical aperture is greatly in excess of the latter lens. Their speed is very nearly the same, especially when transmitted light is used. The

greatest difference between their performances is to be found in the actual field of view which they can embrace and properly define. The 3in. achromat will take in the whole of an object not exceeding $\frac{3}{4}$ in. in diameter, and define it perfectly to the margin without any approach to "fuzziness." The 75 mm., according to Zeiss's catalogue, will "cover and photograph an object 1 $\frac{1}{4}$ in. by 1 $\frac{1}{4}$ in. at full aperture, and 2 $\frac{1}{4}$ in. by 2 $\frac{1}{4}$ in. when stopped down with the iris diaphragm." This is probably correct, but I have had no opportunity to verify it, since the largest opening in the stage of their photo-micrographic microscope is only 1 $\frac{1}{4}$ in. in diameter (one of the numerous defects in this much over-rated stand), which renders the large body, specially designed for using the three larger sizes of micro-planars, of but little practical value. But these may be used very effectively on an ordinary camera with sufficient bellows extension for photo-micrographing opaque objects of sizes named above. They are also excellent for small photographs of landscapes, etc., if one has a camera which can be closed sufficiently for their short foci. At least, the 75 mm. may be thus employed, as I have found in actual use, from which I infer that both the 50 mm. and 100 mm. are equally available for the same purpose.

As these remarks would lose much of their interest and possible value without illustrations, I have made a few comparative negatives from subjects suitable to test both lenses under varying conditions of illumination and amplification, reproductions from which are submitted herewith. The opaque specimens were photographed with an upright camera, and lying flat on the microscope stage, all the apparatus being placed close to a window with western exposure, and the illumination effected by diffused daylight reflected evenly by their surfaces, with no shadows. It is a matter of regret that the shortness of camera extension—just 2ft.—prevented a greater amplification than seven diameters with these lenses of 3in. focus. And here may be noted a point of decided superiority in the micro-objective over the micro-planar. The former lens may be used in conjunction with an eye piece, materially increasing its amplification, with a short bellows camera, whilst the micro-planar cannot be so employed, its construction not admitting the use of an ocular. Hence, as it was necessary for the purpose of comparison to employ the same amplification with both lenses, I found myself restricted in its extent to the limitations imposed by the micro-planar. As illustrative of this important fact, it seems proper to add to the pictures of opaque objects at equal amplifications a third one of same subject, more highly magnified by means of an eyepiece used with the 3in. micro-objective.

A perusal of the foregoing brief remarks, together with careful comparison of the accompanying illustrations, will, I think, convince any one that I have at least good ground for contention that the micro-planar is not the superior of a good or first-class achromatic micro-objective, even in the limited field to which the former lens is restricted. It has its sphere of usefulness, undoubtedly, and some work may be done with the lower powers that is not possible to a microscope achromat, but such instances are rare, whilst I have never attempted work in any field common alike to both in which the performance of the microscope objective was not equal, or just a little superior, to that of the micro-planar. To be sure, my experience with the latter has been confined to the 3in., but it is in these low powers that one would naturally expect to find the great superiority of this form of lens—if such existed. In the higher powers, up to $\frac{3}{4}$ in., the greater numerical apertures of the microscope objectives must give them an immense advantage over the micro-planars, to say nothing of their adaptation to use with eyepieces.

Mr. Pigg's article concludes with this summing up: "The

Fig. 1.—Star Fish. + 7. Photo-macrographed with Zeiss' Micro-planar lens. 75 mm.=3 in. Opaque.

Fig. 2.—Star Fish. + 7. Photo macrographed with Beck's 3 in. microscope objective. Opaque.

Fig. 3.—Star Fish. + 12 Photo-micrographed with Beck's 3 in. microscope objective and aplanatic ocular. Opaque.

Fig. 4.—Egg of Butterfly. + 25. Photo-micrographed with Beck's 3 in. microscope objective and aplanatic ocular. Opaque.

foregoing illustrations prove that, though in some cases the microscope objective is superior to the anastigmat lens, the latter is, as a rule, the superior instrument for photo-micrographic purposes." My own experience seems to lead to the opposite conclusion—that in a limited number of cases the anastigmat lens or micro-planar may be superior to the microscope objectives, but, broadly speaking, the latter, as a rule, is vastly the superior instrument for photo-micrographic purposes. Where cost is of no special moment, the addition of a low-power micro-planar to one's battery of lenses is doubtless desirable, but for the majority of workers not so favoured by fortune, it would be a great mistake to invest in this alone, under the mistaken impression that he was thereby

providing himself with the "superior instrument." But I must conclude, and allow the illustrations to speak for themselves.

Fig. I. A star fish, made with the micro-planar lens of 75 mm. focus. Opaque, illuminated by diffused daylight.

Fig. II. The same subject, photo-micrographed with Beck's 3 in. microscope objective; illumination and all other procedures same as with Fig. I; exposure of each ten seconds. The distance from top to lower visible surface of specimen is over one-eighth of an inch. Both are well defined, but the sharpness throughout would seem to be slightly greater in this one by the achromat.

Fig. III. This illustration is given to shew that the micro-

Fig. 5.—Wing of Mosquito. $+15\frac{1}{2}$. Photo-micrographed with Beck's 3-in. microscope objective. Transparent.

Fig. 6.—Wing of Mosquito. Photo-micrographed with Zeiss' micro-planar lens. 75 mm. = 3 in. focus. Transparent.

Fig. 7.—Proboscis of Blow Fly. $+23$. Photo-micrographed with Beck's 3-in. microscope objective. Transparent.

Fig. 8.—Proboscis of Blow Fly. $+23$. Photo-micrographed with Zeiss micro planar lens. 75 mm. = 3 in. focus.

scope objective may be used with an ocular to increase its amplification, without any impairment of the defining or penetrating qualities. With the short camera the limit of the micro-planar was reached at $+7$, being the same as that of the microscope objective projecting the image without an eyepiece. By merely adding the latter—not possible with the micro-planar—the amplification was almost doubled without loss of definition. Time of exposure was also doubled—20 seconds.

Fig. IV. Egg of butterfly, also an opaque object, magnified $+25$ diameters, with the same optical arrangement as used on Fig. III., and bellows length increased some six inches. At this power the penetration of the objective seems to continue good.

Fig. V. Wing of mosquito, magnified $15\frac{1}{2}$ diameters with Beck's 3in microscope objective.

Fig. VI. The same subject, $+15$ diameters, with Zeiss's

micro-planar lens, 75 mm. These were made under precisely the same conditions. Rapid orthochromatic plates, ground glass screen, and electric arc as radiant. Exposure, one second. The delicate hairs on lower edge of wing, and other markings, are rather better shown by the micro-objective than by the planar.

Fig. VII. Proboscis of blow fly, $+23$. Made with Beck's 3in. microscope objective.

Fig. VIII. This is same subject as preceding, and was photographed with Zeiss's micro-planar lens, 75 mm. Plate, radiant, and exposure alike—rapid orthochromatic, electric arc, and two seconds. Screens were ground glass and aurantia, dyed rather deeply. Details decidedly better shown in Fig. VII. than in the other, especially the membrane of the palpi.

W. H. WALMSLEY.

THE VERANT, A NEW INSTRUMENT FOR VIEWING PHOTOGRAPHS FROM THE CORRECT STANDPOINT.

[A Paper read before the Royal Photographic Society.]

THE representation of a solid object on the ground glass of a camera is not an image in the optical sense, in so far as it is not conjugate to the object with regard to the lens. In fact, looking more closely into it, we behold a kind of projection similar to representations yielded by a pin-hole camera, and moreover, we may easily watch this projection at the side of the objects, if we suppose the camera lens as an ideal objective, free from distortion, astigmatism, and curvature of field.

The image plane is of course determined by the ground glass, and we shall refer to it as to the "ground glass plane." In consequence of the general optical laws, there is one plane only at the object side conjugate to the ground glass plane. As we all know, from the use of the optical lantern—the distance between lens and slide being given—there is only one position of the screen where the diapositive will appear at its sharpest. In our general case, we will call this plane "the plane focussed

Fig. 1.—Projection by means of a pin-hole camera.

for," and we know by experience that it is generally at a considerable, sometimes at an infinite, distance from the lens. None but the points of this plane focussed for are optically conjugate to points of the ground glass, and are rendered there as sharp points, whereas object points before or behind the plane focussed for, are represented on the ground glass as circles of indistinctness. They are formed because the ground glass intersects each image-forming pencil of definite aperture, not in its apex, but before or behind it. The object to these circles of indistinctness is obtained by looking for intersection between the conjugate object plane, i.e., the plane focussed for—and the image-forming pencil before entering the lens. In this way, every circle of indistinctness can be constructed at the object side, and the whole function of the lens consists in optically rendering on the ground glass in n -fold reduction the delineation on the plane focussed for.

Assuming, therefore, rays emanating in every direction from the different object-points behind, in or in front of the plane focussed for, the question now arises which of these enter the objective, and the answer is, all the pencils passing the aperture in the diaphragm. This is easy enough in the case of objectives

with a stop in front; if, however, the stop is enclosed between two lenses, the pencils must be directed towards the image of the diaphragm formed by the front combination; in the same way an observer at the object side cannot see the stop itself, but its image formed by the front lens. As not more than one image of any object is produced by an optical system, only such rays as aim at this image will pass after refraction through the

Fig. 2.—Delineation on the plane focussed for.

stop itself. We will call, with Professor Abbe, this image of the diaphragm the entrance pupil of the system.

Apart from its importance with regard to sharpness, the entrance pupil governs the perspective of the photograph; not only

Fig. 3.—Entrance pupil governing the perspective.

the object-points themselves lie on pencils which pass through the centre of the entrance pupil, but also the centres of the circles of indistinctness, by which object-points outside the plane focussed for are represented on this plane. Any alteration of the diameter of the entrance pupil is followed, with regard to the circles of indistinctness, by a proportionate range of their diameters, but the position of their centres is quite independent

of this alteration. Assuming now objectives considerably stopped down, the projection on the plane focussed for will appear sharp, as thin pencils only will pass through the middle of the entrance pupil. This centre, therefore, will serve as the centre of projection for the objects, the station point.

Considering the image formed on the ground glass as the n -fold reduction of the delineation on the plane focussed for, we do not find any difficulty in placing a print between the station point and the plane focussed for so that they exactly correspond. The pencil from any point on the plane focussed for, aiming at the centre of the entrance pupil, will meet the transposed print exactly in its conjugate point, and vice versa, each ray connecting the station point with any point of the print will when continued reach the respective object-point.

The distance between the print and the station point depends on the focal length and the construction of the camera lens, but here it will suffice to know that it is equal to the focal length when we restrict ourselves to landscape photography where the scale of reduction, if not infinite, is at any rate a high number. We will call this distance "the correct viewing distance," and

Fig. 4.—Centre of the entrance pupil serving as the station point.

it must be realised if we wish to obtain an impression corresponding with nature. For then only will the pencils from the points of the print include at the station point the same angles as were formed at the centre of the entrance pupil of the camera lens when the photograph was taken.

Before we begin to apply these theoretical rules in practice for viewing photographs taken with the ordinary—non-steroscopic—camera, we must mention one rather self-evident point. As there is naturally in such photographs one station point only, it is important that the picture should be inspected by one eye only. Apart from this, the binocular inspection of an apparently plane picture, held at a short distance, will lead us to the notion of a plane object, and this will forcibly contend against the apprehension of relief.

It is prescribed by a sufficiently well-known rule, to bring the observer's eye—more exactly the centre of its pupil—into the station point, in order to obtain on the retina equally sized images as are formed in inspecting the natural landscape. This is certainly correct, but nevertheless the impression gained in this way will not be quite true to nature, because we are not

accustomed to inspect natural objects with a motionless eye, on the contrary, we direct our eye successively to each part of

Fig. 5.—Print properly placed with regard to the delineation on the plane focussed for.

the objects, so that for the estimation of apparent magnitude, the angles are important which are formed by consecutive directions of the axis of the eye when revolving on its centre of rotation. The old rule, therefore, has to be accordingly altered so that not the pupil of the eye but its centre of rotation is to coincide with the station points.

The distance between print and cornea being diminished by 10 to 11 mm. again, it is the more impossible for a normal eye with a distance of distinct vision of 25 cm. (10 inches) to correctly view the majority of existing photographs, as they are taken with lenses of too short a focal length. There are, of course, ways of getting out of this difficulty. As far back as 1844 Geo. S.

Fig. 6.—Apparent alterations of depth and of form due to increased distance between eye and print.

Cundell,* with a view to pleasant perspective, recommended photographic objectives of considerable focal length; or ordinary photographs could be magnified to such an extent that the correct viewing distance became equal to or larger than 25 cm. (10 inches). But both remedies have their serious drawbacks; either expensive, unwieldy cameras or troublesome manipulations are necessary.

When, however, disregarding these remedies, the normal eye is brought into an incorrect (too great) distance from the photograph the impression is a wrong one, as it is untrue to nature. As may be inferred from simple laws of perspective, the possible deception will lie between the two following limits; firstly, the observer, knowing the real distance between the objects represented on the photograph, apprehends near objects too large, distant objects, too small; secondly, the observer, knowing the real relation of height and breadth of the objects represented apprehends too great a depth. These alterations of perspective are perfectly known to every photographer.

A short-sighted person is often able, by the near distance of

Fig. 7.—Diagram of the Verant lens.

distinct vision to inspect from the correct viewing distance, an ordinary photograph (taken with a short focus lens); the impression gained in this way will be perfectly true to nature as far as regards perspective, only the distinctness of vision is greater and the accommodating innervation may be different. The innervation forms, however, but a very rough means of estimating distance, and the impression will hardly be altered when this sensation is at variance with the ordinary state of things.

We are now prepared for the following question: How might a normal-sighted person, in looking at ordinary photographs, not only enjoy the advantage of the short-sighted, but at the same time preserve the correct state of accommodative innervation? This may be achieved by means of an alteration of the second expediency, mentioned before, that is, by replacing the physical magnification by a virtual one. In accordance with Professor A. Gullstrand, we will put forward the following proposition; to construct a viewing glass with the object of forming a virtual, distant, orthoscopic image of a print brought into its front focal plane. The crossing point of the principal rays must at

the same time lie at such a distance from the nearest lens as to be accessible to the eye's centre of rotation.

Further, Professor Gullstrand,* according to rough calculations, proposed a type of lens fulfilling these conditions and requested the Carl Zeiss firm to take up this inquiry. This was after a time done, and a patent was applied for in the spring of 1903 for two binary systems showing a print in the front focal plane to an eye accommodating for infinity, free from colour and distortion. Systems of this kind are used in the instruments I am going to bring before you, and they were called Verant lenses from the Latin: *verus* = true. From the foregoing, you will know that, made of the focal length of the camera lens they will produce the same impression in which an eye at the place of the camera lens would be affected by the objects themselves.

These lenses are free from astigmatism, but not from curvature of field which has the same character as in photographic objectives of older type. In consequence of this, the central part of a print in the front focal plane will appear at infinite

Fig. 8.—Single Verant standing on its handles, with holder for unmounted prints. The unsymmetrical cap is adjusted in the drawing for the left eye. It is important to bring the instrument as close as possible to the eye. When used with the right eye the cap has to be turned 180 degrees.

distance, whereas the margin will appear nearer. Inspecting in the Verant the margin of a print we must therefore alter our accommodation for the central part. This is done spontaneously by young and middle-aged people, whereas an elderly person will have to alter the focus for the margin. Short-sighted people are advised to use their ordinary spectacles; they will, of course cause the inherent distortion which, however, is generally overlooked.

Summing up, we come to the following conclusions: supposing we have a Verant lens of the focal length of the camera objective, a normal eye will obtain, through the Verant, as far as perspective and accommodation is concerned, the same impression it would obtain from the natural landscape when brought to the place of the entrance pupil of the camera lens. And if colour is neglected the impression caused by the photograph will exactly correspond with that exercised by the natural objects.

This necessarily affects our apprehension of relief, and our

* On the Practice of the Calotype Process of Photography. *Phil. Mag.*, 1844 (3), 24, 321-332.

* According to a letter of July 6th, 1902, Professor A. Gullstrand claims priority for "das P. in der Verlegung des Knotenpunktes für die axialen Strahlen der austretenden Lichtschmelze in den Drehpunkt des Auges und das Prinzip der Zusammensetzung aus zwei Menschen mit Brechkraft und Biegung von entgegengesetzten Vorzeichen."

estimation of distance must correspond with the conclusions we should derive from monocular inspection of the objects themselves. Accepting Sir David Brewster's* distinction between the criteria of distance and the seeing of distance, we can obviously not see distance by monocular vision without accommodative innervation, but we are restricted to the four first criteria of distance, i.e.,

1. The interposition of numerous objects between the eye and the object.
2. The variation in the apparent magnitude of known objects.
3. The degree of variety in the colours and tints of objects.
4. The degree of distinctness in the outline and minute parts of objects.

All these with partial exception of the third, apply equally to monocular inspection of a photograph in the Verant, and they exert in this case on our mind the same powerful influence as solid objects do in monocular vision; to use Sir David Brewster's words, "the monocular relief" of a photograph in the Verant is obvious. We are, therefore, justified by this impression of solidity, in concluding that the criteria of depth are of much greater importance than is generally conceded to them. At the end of our lecture we shall point out another instance in favour of this conclusion.

When the Verant lens has a focal length different from that of the camera objective, the perspective of the print is altered; in the case of a longer Verant focus, the possible alterations correspond to the extreme cases already enumerated when dealing with the wrong impression conveyed to a normal eye by a short focus picture. In the case of a shorter Verant focus, the possible alterations are exactly the reverse, as the angles of vision become larger than the angles at the entrance pupil of the camera lens. The conditions are now precisely as in the case of a field glass, for it is the very function of a telescope to enlarge for the observer's eye the angles at the object side enclosed between the axis and the pencils entering the objective serving here as the entrance pupil of the telescope. It is probably due to the very limited extension of field in the telescope that this alteration of perspective is not better known, for the whole field of a telescope of say four diameters will hardly exceed 10 degrees. Using glasses of still less power in opera glasses, for instance, sometimes not more than $1\frac{1}{2}$ diameter is realised—the angles at the object side are certainly increased, but at the same time, their telescopic alteration becomes too inconsiderable to enforce itself as a deterioration of perspective. For our Verant lens, we may easily infer from this example that we need not be too particular in choosing its focal length in accordance with that of the camera objective. We have therefore planned two different Verant foci, one of 11 cm. ($4\frac{1}{4}$ -inch), and one of 15 cm. (5 9-10-inch). If we allow for the equivalent focal lengths a discrepancy of 1 : 6.5 = 15.4 per cent., the former Verant lens will suffice for objectives from 9.3 cm. ($3\frac{3}{8}$ inches) to 12.7 cm. (5-inch), and the latter from 12.7 cm. (5-inch) to 17.3 cm. (6.82 inches). Our Jena experiments showed for differences of such order, no appreciable alteration in our apprehension of relief; or in other words, the alteration due to such differences is not apparent to the average observer if he judge from memory alone without comparing the impression gained in the Verant with the impression produced by the objects themselves.

On this occasion we will point out the help to the better understanding of the principle of the telescope for which the Verant lens, of different focal length may be applied. Camera objective and Verant lens repeat the entire function of the telescope as regards perspective, but as the part of the objective

is separated by a certain space of time from that of the eye-piece, both are more easily understood; the camera lens acts as the telescopic objective, and the print takes the place of the aerial image formed behind the objective; as it has physical existence, it can be lighted sufficiently so that a regulation of the way of the pencils by means of a field lens is unnecessary. The eye-piece is replaced by the Verant lens forming a distinct image of the print for a normal eye accommodating for infinity. If, for instance, a Verant lens of 11 cm. be used for inspecting a photograph taken with an objective of 44 cm., the function of a four-fold telescope is illustrated with the difference, however, of a field not restricted to 10 degrees but extending beyond $16\frac{1}{2}$ degrees. In proportion to this enlargement of field, the alteration of perspective will be more clearly apprehended; as the print can be viewed with the naked eye from the correct standpoint, one is able at any time—not being restricted to natural objects—to compare the impression obtained from one standpoint by means of the naked eye with the impression obtained from the same standpoint through a field glass of four diameters.

It was only natural to apply lenses of this description to binocular instruments. Let us suppose two Verant lenses

Single Verant. In use, the handles are brought together and clasped in the four fingers.

arranged at a distance of about two inches of their parallel axes (the lower limit of interocular distances occurring) we immediately see that short foci alone are applicable; otherwise the prints would either hinder each other, if anything approaching a considerable field of view were required, or plane mirrors would have to be applied. We disregarded, however, this expediency first used in Wheatstone's classical stereoscope, because a double Verant provided with mirrors could by no means have been adapted for paper prints, but would have been restricted in consequence of the difficulty of lighting to the exclusive use of transparencies.

Let us for a moment suppose that ordinary transparencies will bear even a high magnification and that Verant lenses of a corresponding short focus could be constructed with so great a distance as 25 mm. (1 inch) between stop and nearest lens. Taking this for granted, the advantage would certainly be with short focus lenses, as the angles of vision subtended to the eye by a clear breadth of, say, 48 mm. (1 9-10 inch) would be correspondingly large. The question now arises, what magnification in diameters will be borne by an ordinary negative? For it is

* *This Stereoscope*, London, J. Murray, 1853, pp 4-56.

the grain of the negative, not of the transparency, which decides the possible magnification. In our experiments we came to the conclusion that, say a three-fold magnification is allowed, whereas ordinary negatives give a decidedly unpleasant effect under a four-fold magnifier. We therefore chose a focus of 73 mm. (2.9 inches) for the double Verant, and in consequence thereof, we see the clear breadth of the transparency under an angle of $36\frac{1}{2}$ degrees, and its diagonal under 50 degrees. With a still shorter focus of the Verant lens—we made a very satisfactory specimen of 63 mm. ($2\frac{1}{2}$ inches) — the angles are respectively $41\frac{1}{2}$ degrees and $56\frac{1}{2}$ degrees. Such lenses would naturally show more clearly the advantage gained by this instrument, but they will not do with directly copied transparencies, and to substitute reduced slides (say to $\frac{1}{2}$ from objectives of 127 mm. (5 inches) in order to reduce the grain of the negative in the same proportion would be too troublesome for the majority of photographers.

In adapting the double Verant to the observer's interocular distance, we must, in accordance with Mr. L. Bolton's able paper, insist that each Verant lens is to be placed exactly opposite the centre of vision of the corresponding print. In the double Verant, we obtained this end by rigidly connecting the lens with the print holder. It is then, of course, impossible to mount these stereoscopic prints in the usual manner.

In using the double Verant (the distance between the camera lenses had been 65 mm. (2.9-16 inches), the impression was quite true to nature, as was ascertained by direct comparison with the objects photographed. In using the same double Verant for pictures taken with objectives of less separation 20 mm. (4-5 inch), near objects appeared larger, whereas their size was apparently diminished in the case of a separation between the camera lenses exceeding 65 mm. (2.9-16 inches). I must, however, mention that in order to show these alterations rather great deviations from the interocular distance were necessary. Following up this connection between apparent size of near objects in the stereoscope and deviation from the interocular distance, it was natural to repeat with our double Verant the old experiment of placing identical prints in the stereoscope. The result was very satisfactory for landscape prints without near foreground. In viewing such with both eyes, the trifling stereoscopic differences, that is the means of seeing distance, are not missed, whereas the criteria of distance are rendered with all truth photography is able to show. Our satisfactory apprehension of relief formed by the inspection of identical pictures is the other proof of my view that the importance of the criteria of seeing is generally undervalued.

DR. MORITZ VON ROHR.

DISCUSSION.

Dr. von Rohr then showed to the audience the instruments to which he referred, and produced some prints for examination. Through the kindness of a friend he was in possession of some London views, so that those present would be able to judge for themselves whether the impression given by means of the instruments was correct or not.

Mr. John Stuart said he had been much charmed with the lecture they had just heard, and thought their thanks were due to Dr. von Rohr for first bringing such a useful and elegant instrument to the notice of the Society. No doubt the instrument would prove, not only a personal, but also a commercial success. To be able to see single views stereoscopically, as was shown by these instruments, was, he thought, quite novel and of great interest, and he would not have believed that such relief was possible unless he had actually seen it himself. The stereoscopic relief when two pictures were used, both

reversed and non-reversed, was very beautiful, and the effects exceedingly natural. He, personally, was very glad that Dr. von Rohr had come such a long distance to show them these interesting devices. With regard to the lecture itself, it was, of course (as was to be expected from Dr. von Rohr) of a mathematical nature, and he thought members would follow and appreciate the various points better when they read it leisurely in print, than in listening to it that evening.

Mr. L. Bolton said that Dr. von Rohr's paper explained why it was that he (the speaker) had failed to obtain the projections of certain surfaces into others by means of the stereoscope to which he had referred at the end of his paper, read before the Society early this year. The failure to do this, the possibility of which was indicated by geometry, was doubtless due to the neglect of the principles on which Dr. von Rohr had insisted, and therefore supported Dr. von Rohr's contentions.

Mr. Philip Everitt said he thought there was one point particularly deserving of emphasis with regard to the double Verant. He referred to the use of the instrument in viewing identical pictures, so as to see them as one picture in relief. This was a very curious effect, and deserving of a great deal of attention. So far as the practice of photography was concerned he thought that an examination of this matter might be found very valuable. With this instrument they might take two prints from one negative, and see them as though they were stereoscopic. An amateur could therefore make use of his entire stock of negatives, stereoscopic or ordinary. If the one chosen should be too large he might reduce it to the size requisite for use in this instrument; and, with two prints from the negative, obtain the effect of a stereoscopic picture without having to go again to the place where the original photograph was taken. He thought this was a very valuable point, and one deserving of a great deal of attention. With regard to the single Verant also, he thought it would prove of very great advantage. They could place a print in this instrument, and see the view as though they were really in the spot where the view was taken, except, of course, that the colour was lacking. They had seen some toys—he must call them toys, for they were not constructed scientifically—somewhat after the style of these instruments, but in the case of the Verant the construction was such that they were enabled to see an exact reproduction of the forms of nature.

Dr. von Rohr expressed his thanks to the audience for the patience with which they had listened to his explanation of the instruments. He was well aware that he could not make the theory of the whole instrument clear in so short a time as three-quarters of an hour; but he thought that if they looked over the paper when printed they would be able to see what he would like to have conveyed to them that evening. He must add that he was indebted in a very great measure to some writers of former times who got upon similar lines before, and whose work had been of great help to him. The first man he referred to was Sir David Brewster, who had done so much in calling attention to binocular relief in the stereoscope; but as he had pointed out in his lecture, he did not think that Sir David Brewster had sufficiently appreciated monocular relief, although he was certainly conscious of its value. Another name he must mention was that of his old and highly valued friend, Mr. R. H. Bow, of Edinburgh, to whom later writers on optics were indebted in a great measure. As far back as 1863* he had constructed an instrument somewhat similar to those before them this evening, adapted for viewing lantern slides. Mr. Bow had been very near to develop, as regards perspective, the importance of the centre of rotation of the eye; but as he (the speaker) had ascertained from Mr. Bow himself, when he had the pleasure

* "On the Advantages of Photographic Transparencies, &c." THE BRITISH JOURNAL OF PHOTOGRAPHY, 1863, 19, pp. 101-102.

seeing him in the spring of 1903, he had stopped just short of this point which was left for Prof. Gullstrand. In later years there appeared some important papers, and he referred especially to H. Helmholtz's treatment of the stereoscope and the telestereoscope.* Among the productions of the last year he must call attention to a valuable paper by a Dutch lieutenant, L. E. W. van Albada.† Then last, but not least, must mention Mr. Lyndon Bolton.‡ In Mr. Bolton's paper the cause of the incorrect reproduction of distances in the stereoscope was mentioned. The eye-pieces were of too great optical length for inspection of the prints. He (the speaker) tried to avoid this, and he had the pleasure of showing one of those present—Mr. Frederic J. Cheshire—stereoscopic slides in this instrument, and of having that gentleman compare these with the objects themselves. He could not show this to all those present, but perhaps some would be interested in taking the objects accessible to all, and they would be able by means of the instruments—which the firm of Carl Zeiss intended to present to the Society—to ascertain the correctness of the views at he had put forward.

Mr. John Stuart asked how soon the instruments were likely to be upon the market, and as to the price at which the instruments were to be sold?

Dr. von Rohr replied that the single Verant would be upon the market from that time. The single Verants would be priced at about 24s. or 25s. each. With regard to the double Verants, it would be some time before they were ready.

The Chairman had pleasure in proposing a vote of thanks to Dr. von Rohr for his very interesting lecture. He cordially endorsed the remarks made by Mr. Everitt regarding the practical use of the instrument, and thought that there could be no doubt that it would be an immense advantage to be able to obtain stereoscopic effects in the way shown from ordinary photographs. With these instruments there would be no need of using a special stereoscopic camera with double lenses as in ordinary work, nor for special mounting for stereoscopic vision. Both the double and the single Verants appeared successful in showing photographs in proper relief and true perspective. On behalf of the Society he wished to thank Messrs. Carl Zeiss for the very handsome donation they had so kindly made to the Society.

Mr. Frederic J. Cheshire said he had been referred to by Dr. von Rohr as having seen and made certain experiments. He thought that what he saw might be of interest to those present. Some weeks ago he had the delightful experience of passing a few hours with Dr. von Rohr, and discussing with, or rather being lectured to by him on the questions that had come before them that evening. At the close of the discussion was taken by Dr. von Rohr upon the flat roof of the building without any intimation being given as to what he was to look for. Standing at a certain spot he was asked to look at a pair of photographs in the Verant, and then compare what he saw with the free-vision views from the same spot. On thus comparing photographs taken with an inter-objective distance of 40 millimetres, his own inter-pupil distance being 71 millimetres, he could not see any difference, except what they could naturally expect to find in a photograph, such as absence of colour, etc. Then he compared photographs taken with an inter-objective distance of 40 millimetres. Immediately on his right was a row of skylights of bee-hive shape, stretching from his feet to the edge of the building, and on looking through the Verant at the photographs taken with the inter-objective distance of 40 millimetres, the only difference he noticed was

that the skylights in the immediate foreground appeared to be larger when seen through the double Verant than in nature itself. Of course, that could not really have been the case; it must have been a subjective impression. Then he took photographs taken with an inter-objective distance of 105 millimetres, and compared them with nature, and under those circumstances the objects in the immediate foreground appeared to be much smaller than in nature. Mr. Cheshire took the opportunity of asking Dr. von Rohr, whom they all knew as the author of a classic book on "The Theory and History of Photographic Objectives," whether there was any likelihood of his book being translated into English in the immediate future.

Dr. von Rohr said that it was very kind of Mr. Cheshire to refer in such an appreciative manner to the book. He was afraid that he could not answer the question. There would be no objection on his part to having a translation, although he would like to make some important alterations in the work; but he was afraid there would be some difficulty in finding an English publisher sufficiently venturesome to publish an English edition of the work.

Mr. W. E. CROZIER has commenced business at 22, Harrison Terrace, Truro, Cornwall, as a photographic dealer.

WE have to thank the Editors of "The Photogram" for a bound volume of that admirable publication for the year 1903.

A CORRESPONDENT writes:—"In looking over a map of Africa to-day I discovered a town marked Kodok, situated near Fashoda, with whom the name of Major Marchand is associated. It would be interesting to be informed if this is a native name or the native pronunciation of this place, or a modern name to an ancient town."

Mr. W. B. SAMUEL, of 87, Clapham Road, London, S.W., writes:—"In your 'Answers to Correspondents' in the last number, 'Largo' asks how to clean daguerreotypes. I have made it part of my business for years past cleaning and restoring daguerreotypes for the profession. I shall esteem it a great favour if you will put me in communication with him."

THE attention of customers of Brin's Oxygen Company, Limited, is directed to the change of the company's address. Elverton Street, Westminster, is a new street connecting Horseferry Road with Vincent Square. The company's works are on the old site associated for the last seventeen years with 69, Horseferry Road, but the old entrance in Horseferry Road has been closed and new entrances opened in Elverton Street. The company has also built extensive offices in Elverton Street to accommodate all their staff, and the Commercial Office at 34, Victoria Street, will therefore be shortly abandoned. In future the exclusive address of the company in London will be Elverton Street, Westminster, S.W. New price lists addressed to the medical profession; lanternists, blowpipe users, and others have been issued by the company, who also publish a neat and useful pocket diary, containing, besides the usual spaces for notes, much technical information for lantern workers.

AN esteemed correspondent writes:—"You have published on different occasions some ways of marking printing frames so as to avoid mistakes when from one negative a certain quantity of prints were needed. I have used several of these, and principally the one going backward, beginning for instance at 100 to finish with one, in which case I saw at first glance how many were yet needed, but the writing of each number was a loss of time. I have now hit on the following idea, which I find more practical and more rapid. I make a square the size of my printing frame and I divide it in ten small squares each way, making 100, and I number them, the first 10 to the left top 100 below 90, and so on until last one is No. 10. Now, upon taking out a print, or if one prefers when putting the paper in the frame to print, I make a pencil mark first on 100, then on the following square to the right, and so on until I have them all filled, and then the 100 or the job, whatever the number may be, is finished, and no possible mistake can happen except such a mistake as can happen with any other method, and in that case unavoidable."

"JUDY" ON THE TANQUERAY SYSTEM.

(Reprinted from "Judy" for the Professional Photographers' Association.)

THE ROTTENOTINT PORTRAIT

Is the Most Marvellous Offer Ever Offered.

A Six Shilling Portrait for Eight and Three-halfpence.

SEND ALL AT ONCE.

To Readers of "Judy."—The Editor is still completing arrangements whereby readers can obtain

A LARGE FULL-SIZE ROTTENOTINT PORTRAIT,

superbly packed in pale blue paper, and secured with pink twine, for the small sum of Eight Shillings and Three-halfpence Post Free on receipt of Six Shillings and Sixpence.

HOW TO OBTAIN THE WONDERFUL PORTRAIT.

All you have to do is to send all at once Nine Shillings and Ninepence, together with your Dog Licence and Birth Certificate. We do the rest. In sending, please state whether for hot or cold climate.

THE FRAME ALONE

Is worth One and Fourpence (2ft. by 3ft.), with full directions how to use it. Testimonials from all the leading Physicians in Drury Lane. Write your name and address plainly in ink (red preferred) and send us Eleven Shillings and Three Halfpence to cover postage. If, after reading this, you fail to understand the price, send us another Shilling and Sixpence. The portrait will not be sent unless desired.

The Rottenotint is a silent process known only to the artist.

"Truth" has given me notices for years.

Two portraits for Three Shillings and One Halfpenny.

Specimens can be seen at the Offices on payment of Seven Shillings and Sevenpence.

The "Morning Leader" says: "Oh, rot!"

Agents Wanted Five Minutes after Portraits are Received.

A FEW TESTIMONIALS.

Dear "Judy,"—Rottenotint to hand this morning. The frame still works a little stiffly, but that, no doubt, is a fault which time alone will rectify. The portrait itself is marvellous. Who is it?—O. O.

Dear "Judy,"—The Rottenotint has not yet arrived, but I gather that it will be here now shortly. The engine has been repaired, and no further breaks-down on the line are anticipated. In order to avoid delay this end, I have arranged to have it conveyed from the Railway in a closed van.—Yours Hopefully, SMITH.

Dear "Judy,"—Rottenotint almost arrived. We can hear it at the top of the street. Many, many thanks! Thanks! Awfully obliged! Delighted, in fact! Thanks!—FLO.

Dear "Judy,"—I have your Rottenotint of the 21st inst., for which please accept my heartfelt thanks. Will you please say whether it should be boiled in hot or cold water. I have looked it up in Nuttall's, but can find no reference to it.—Yours truly, A. S. S.

Dear "Judy,"—My wife and I have now returned after the long sea voyage recommended by medical experts, and are, therefore, quite prepared to receive Rottenotint. Wire as soon as dispatched. We hope for the best.—Yours Confidently, THOS. JAY.

PUBLISHERS of works of fine art and of photographs suffer greatly at the hands of pirates; but, evidently, not to the extent that the music publishers do, for the Musical Copyright Association report that during the month of December 140,855 pirated copies of music and 22 sets of pirated plates have been seized, which shows the extent of the illicit music trade. In spite of these extensive seizures this illicit trade still goes on.

Exhibitions.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

THE ninth annual exhibition of the Borough Polytechnic Photographic Society was open to the public on each evening of last week at the Borough Polytechnic, Borough Road, S.E.

Although this year's exhibition was perhaps slightly in advance of last year's, we cannot say that the work generally impressed us with the idea that the members are making the progress in artistic knowledge that might reasonably be expected. From the constitution of the society it follows that the bulk of the exhibits would be efforts of beginners, and from that standpoint the exhibition showed that the elementary factors in practical photography are as well taught as of yore, and it was as good as ever in the display of technical ability but there is certainly a check in pictorial progression. The landscape class undoubtedly manifested retrogression rather than progression, and it is hardly too severe criticism to say that not a single photograph in it was up to what ought to be the standard of acceptance of the Royal Photographic Society's exhibition. Many of the members seem to have devoted their principal efforts to architecture, and the work in this branch of photography was admirable in quality. Pictures of more than average excellence were shown by E. R. Bull, J. W. Hodges, F. W. Mundy, H. V. Abbott, T. R. Somerford, F. W. Gregg, and W. Page. We were pleased to notice a decided increase of interest in figure studies, and much of the work was obviously the result of careful arrangement and not merely of the haphazard kind that has constituted the usual filling of the class in most exhibitions heretofore. Many of the pictures had commendable points, and, judged by the standard of what we have been accustomed to meet with in members' classes at exhibitions, was decidedly good. The prevailing faults were those due to inexperience in methods of treatment, and in applying those methods which are well understood in dealing with landscapes, etc., to subjects of so different a character. Some of the best work in the class was by A. J. Bullock, E. W. Burch, J. W. Francis, W. Page, F. W. Gregg, and G. Wynne. The interest taken in architecture was strongly indicated in the lantern slides, the majority in number and the best slides being architectural subjects. In addition to the competitive classes there was an excellent exhibit of work of veterans of the society, most of the pictures having been exhibited at previous exhibitions, and there were trade exhibits by the Rotary Photographic Co., Kodak, Ltd., Wellington and Ward, the Prosser-Roberts Co., and Tyler Bros. and England.

The judges were Mr. srs. C. Churchill, J. A. Hodges, and W. Thomas.

THE AWARDS.

Landscape, etc.—Silver medal, H. C. Philcon; bronze medal, A. Hopkins.

Architecture.—Silver medal, F. W. Gregg; bronze medal, W. Page. Portraits, Figure Studies, Flowers, Animals, etc.—Silver medal, G. W. Francis; bronze medal, H. V. Abbott; honourable mention, G. Wynne. Lantern Slides.—J. W. Hodges (two awards).

EXHIBITION AT WISHAW

DURING the New Year holidays the Wishaw and District Amateur Photographic Association (Federated with the Scottish Photographic Federation) held an "Arts and Crafts" Exhibition in the Public School. Here photography holds the premier position, no less than nineteen classes being allotted to it, while close on three hundred entries are forward.

The open classes show some excellent work, quite a number of prominent exhibitors being represented; while the members' classes show a satisfactory improvement on last year, several of their classes containing really fine work. The judges were Mr. J. W. Eadie and Mr. Archibald Campbell, Scottish Photographic Federation judges, and Mr. John B. MacLachlan, Secretary to the Federation.

The following is the full list of awards:—

Open Class.—Portraiture—1, Alex. McDuff, Glasgow, "A Study";

Dan Dunlop, Motherwell, "Portrait Study;" 3, John A. W. Fryer, Wishaw, "Pensive."

Open to Amateurs.—Championship Gold Medal—William Clayden, Plymouth, "A Misty Morn." Landscape or Sea Cape—1, William Layden, Plymouth, "A Gleam of Light;" 2, W. S. Crocket, Glasgow, "A Bend in the Road;" 3, A. W. Walburn, West Hartlepool, "A November Afternoon." Flowers, Fruit, or Still Life—1, Robert Burnie, Glasgow, "Roses;" 2, Alexander Sandilands, Wishaw, "Almond Blossom;" 3, A. Walburn, West Hartlepool, "Ivy Geranium." Architecture—1, W. A. Clark, Birmingham, "Crypt, Winchester;" 2, William Milroy, Glasgow, "An Aisle;" 3, Arthur Marshall, Nottingham, "A Pillar of the Church." Enlargement—1, John Smith, Hastings, "Weary, Worn, and Sad;" 2, Arthur Marshall, Nottingham, "Sunday Morning at Whitby;" 3, R. B. Spanswick, St. Albans, "A Summer Morn." Lantern Slides (set of three)—1, William Milroy, Glasgow; 2, Rev. E. Travers Clark, Newham-on-Severn; 3, George A. Booth, Preston. Stereoscopic Prints or Transparencies (set of four)—H. Wormleighton, Leicester.

Confined to Burgh of Wishaw and Parish of Cambusnethan.—Any subject (Boys and Girls under Sixteen)—1, A. Macintyre; 2, Andrew Muir. Any Subject (Confined to Ladies)—1, Miss M. B. Pettigrew.

Confined to Association.—Landscape or Seascape—1, Alexander Sandilands; 2, James Fallow; 3, Richard Sneddon. Flowers, Fruit, or Still Life—1, Alexander Sandilands; 2, Thomas Peat. Animals—1, Alexander Sandilands; 2, R. Sneddon. Snapshots of Objects in Motion—1, Adam Allan; 2, W. Sandilands. View taken in the Burgh of Wishaw—1, R. C. Macdonald. Portraiture—1, John A. W. Fryer; 2, J. Fallow; 3, N. S. McMurtrie. Enlargement—1, J. Fallow. Lantern Slides—1, Alexander Hinshelwood, Jun.; 2, Alexander Symon.

Confined to Members who Received no Awards at First Exhibition.—John A. W. Fryer; 2, Adam Allan. Best Mounted Photograph—J. Fallow.

FORTHCOMING EXHIBITIONS.

January 8-9.—Holmfirth and District Photographic Society.

February 10-13.—The Longton and District Photographic Society. Hon. Secretary, T. Mottershead, 43, Stafford Street, Longton, Staffs.

February 13-27.—Scottish National Photographic Salon. Exhibition Secretary, Alex. Mackenzie, 42, Scott Street, Perth.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Hadwell, Essex.

March 5-12.—Brechin Photographic Association. Hon. Secretary, J. Kirk, 1, Infirmary Street, Brechin.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

SECONDARY Radiation produced by Radium Rays.—I lately had occasion to produce some radium radiographs of two partially overlapping pennies contained in a paper envelope which was laid directly upon the photographic plate. A print from one of the results shows that the shadow of the upper coin is blurred and diminished where the rays pass through air from the edge of this coin to the plate, but that it is sharp and of the correct size where the rays pass to the plate through the lower coin. This seems to point to the production of a considerable secondary radiation by the rays in their passage through air.—L. R. Wilberforce in "Nature."

Patent News.

The following applications for patents were made between December 21 and December 31, 1903:—

Developing Chambers.—No. 27,942. "Improvements in photographic developing and changing chambers." Alfred William Southey.

Shutters.—No. 27,962. "Improvements in shutters for photographic cameras." The Thornton-Pickard Manufacturing Company, Ltd.

Stereoscopic Views.—No. 27,971. "Improved means for taking stereoscopic photographic views." Claus Matthiesen.

Exposure Meters.—No. 27,986. "Improvements in or relating to actinometers and photographic exposure meters." (Date applied for under Patents Act, 1901, 12th May, 1903, being date of application in France.) Complete specification. Edouard Degen.

Trichromatic Photography.—No. 28,001. "Improvements in the production of negatives for trichromatic photography." Thomas Knight Grant and Frederick Joseph Stedman.

Frame Closures.—No. 28,044. "Improvements in spring closures for photograph and like frames." Wilhelm Bloesser.

Enlarging Apparatus.—No. 28,168. "Photographic enlarging apparatus." Complete specification. Young Shannon.

Shutters.—No. 28,319. "Improvements in and connected with focal plane shutters for photographic cameras." Charles Edwin Pollard.

Shutters.—No. 28,358. "Improvements in or relating to focal plane or other roller blind shutters for photographic purposes." Arthur Lewis Adams.

Lantern Slides.—No. 28,364. "Improvements in optical magic lantern and other slides and pictures." Theodore Brown and Ernest Osman Brown.

Light Filter.—No. 28,410. "An improved photographic-ray filter." (Rollin H. Stocoum, United States.) Percy Richard Julius Willis.

Film Holder.—No. 28,538. "A new or improved device for holding photographic films, papers, and the like during the process of washing or developing." John Wilkinson and Alfred Wilkinson.

Developing Apparatus.—No. 28,750. "Improvements in apparatus for developing photographic plates or films." Complete specification. Norman Somerville Brodie.

Photos.—No. 28,766. "Improvements in photographic pictures." Samuel Henry Crocker.

Shutter Attachment.—No. 28,792. "New or improved means for attaching to photographic shutters, mechanism for the transmission of power in varying directions for the purpose of releasing or operating such shutters." Charles Henry Watson and Arthur Henry Edwards.

Colour Photography.—No. 28,798. "Improvements in and connected with stereoscopic colour photography." Charles Louis Adrien Brasseur.

MR. J. TILFORD writes:—Many thanks for the "Almanac." I was much pleased to see the articles in favour of wet collodion and albumen paper, both processes having always been favourites with me. I have some prints on the latter made in 1858, that show little signs of fading, although at that time I had not much knowledge of the conditions conducive to permanence.

THE death on December 19th, 1903, at Hove of Mr. John Henry Brown recalls the little-known fact that, as the inventor of the iris diaphragm, he has laid the scientific world under a considerable obligation. "In the early seventies," Dr. Hollis writes from Hove, "he took his home-made model to Smith and Beck, the predecessors of the well-known firm of opticians in Cornhill. This model he showed me, many years ago, and although roughly constructed it differed in no important detail from the type of apparatus at present in the market. As he did not patent the little contrivance he reaped no pecuniary reward for his ingenuity. Although frail in body and physically somewhat infirm, Mr. Brown by indomitable energy made and retained for many years a large practice as a dental surgeon. He was a fellow of the Royal Astronomical Society, and died aged sixty-seven, much respected.—"Nature."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
8	Aberdeen Photographic Assoc.	<i>Development of Slides from Black to Warm Tones.</i> Mr. G. R. Ford.
10	South London Photo. Society...	<i>Excursion to Chigwell.</i> Leader, Mr. G. Brown.

14	Hull Photographic Society	<i>V.P.U. Slides, No. 2 Set.</i>
14	Liverpool Amateur Photo. Assoc.	<i>The Black-Smith Method of Toning.</i>
14	Liverpool Amateur Photo. Assoc.	<i>Byomide Prints.</i> Practical Demonstration. Mr. A. C. Batty.
14	Liverpool Amateur Photo. Assoc.	<i>Lantern in Use for Testing Slides.</i>

ROYAL PHOTOGRAPHIC SOCIETY.

ELECTION OF OFFICERS, COUNCIL, AND EXHIBITION JUDGES.

(Extracts from the Articles of Association.)

Art. 21.—The officers of the Society shall be a president, four vice-presidents, a treasurer, a solicitor, an Editor of the Journal, and a secretary. All the officers except the secretary shall be elected from the members. The secretary may be a member. All offices shall be honorary except those of Editor of the Journal and of the secretary, either or both of which may be honorary or not at the discretion of the Council.

Art. 29. At least one half of those elected on the Council shall be Fellows of the Society.

Art. 46.—The election of the officers and Council, other than the officers appointed by the Council, shall be by a ballot of all those members of the Society who are entitled to vote. Such officers and other members of Council as are elected by the members shall retire annually and shall be eligible for re-election. Every member of the Society who is entitled to vote shall have the right to nominate one member as president, four members as vice-presidents, one member as treasurer, and twenty members as ordinary members of Council. . . . No member shall be eligible for nomination to the Council unless he shall have paid his subscription for the previous year.

Art. 37.—All nominations must be sent to the secretary not less than twenty-five days before the annual general meeting. . . . The annual general meeting will take place on Tuesday, February 9th, 1904.

The election of the exhibition judges will take place simultaneously with that of the officers and Council.

The Standing Orders provide that there shall be five judges in the Pictorial Section, and that they shall be members ex officio of the Pictorial Selecting and Hanging Committee, which will be made up to twelve members by the Council. In the Scientific and Technical Section there will be seven judges elected by the members, the same forming the Scientific and Technical Selecting and Hanging Committee.

A form of nomination is sent to each member. It may be returned at any time before, but not later than, January 15th, 1904, and should

be addressed to the Secretary, Royal Photographic Society of Great Britain, No. 66, Russell Square, London, W.C.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

DECEMBER 31st.—Mr. T. E. Freshwater in the chair. The secretary read the programme for the ensuing three months, and urged the members to help the officers to maintain and increase both membership and attendances, at the meetings so that the committee would be able to keep up the standard of papers submitted. In the discussion that ensued Mr. Drage and others were of opinion that the London and Provincial had a better average attendance than the most societies. Mr. Mackie thought not, and pointed out that other societies had larger attendances because they went in for pictorial photography, a subject that the London and Provincial did not touch, nor did the society take any interest in practical work of any kind, and

suggested that pictorial exhibitions be organized. Mr. Everitt also is of opinion that comparative trials of plates, developers, orthochromatic work, etc., would tend to quicken interest in the society's meetings. The discussion was here adjourned till next week. The chairman then presented the gold medal of the Henderson Award to Mr. Thorne Baker, which had been awarded him by the committee.

Mr. Thorne Baker thanked the association for the medal, and for the general courtesy always extended to him at the meetings.

Mr. Baker opened a discussion on halation, dispersive and reflective. On the course of a closely reasoned address Mr. Baker said he had found that isochromatic plates were not so liable to the effects of halation as were ordinary plates; that the addition or omission of a thin layer of silver made little or no difference, nor had he found it necessary that the refractive index of the backing compound and the glass plate should agree. The backing must be in optical contact with the glass, and that red or black backing were best, brown not having any absorbing power.

Mr. Everitt and Mr. Haddon disagreed with Mr. Baker on the influence of the refractive indices of backing and glass plates, and were of the opinion that unless these did agree the full advantage of the backing could not be obtained.

On the motion of Mr. Drage the hon. secretary was instructed to write a letter to the relatives of the late Mr. Frederick York, who had always been a good friend to the London and Provincial, and whose death was a great loss to photography.

SOUTH AUSTRALIAN PHOTOGRAPHIC SOCIETY.

The exhibition of this society was held last autumn. The exhibits were on view for a week, during which time there was an excellent attendance of visitors, resulting in a considerable increase of the society's funds. More than 300 pictures were hung, nearly double the number shown last year. They included exhibits from England, India, Cape Town, the Australian States, and New Zealand. The Cape Town society was well in the front with about sixty entries. The room of the Society of Arts (in which society the Photographic is affiliated) proved none too large, but was eminently suitable, owing to the overhead lighting. The feature of the exhibition was the marked absence of glossy prints, whose place had been taken by work on matte surface papers, carbon and gum bichromate, resulting in a display of artistic and broad effects. The judges were Messrs. J. Kaufmann, H. P. Gill, and A. A. Stump for the general classes, and Messrs. Andrew Scott, W. P. Dollman, and H. Kingborough for the lantern slides. In Section I. (open to members of the S.A. Society only), the exhibits were somewhat disappointing, both as to number and quality, and in this respect the exhibition was not representative of the capabilities of the society; the few studies were, however, an exception, and compared well with those entered in Section II. (open to members of any photographic society in the world). A new class was introduced in the prospectus in accordance to the wishes of some members, viz., "unretouched prints in untouched negatives," and several exhibits were on view, a landscape by Mr. F. A. Joyner winning the bronze medal. No award was given by the judges to the hand camera class, nor to architecture (in either section). The silver medal for the best picture in Section I. was won by Mrs. M. Jay for a portrait entered under "ladies' class." In Section II., the largest number of exhibits was in the landscape class, over eighty pictures being hung; the silver medal was awarded to Stanton Browne, of Tasmania. There must have been great difficulty in the judging of this class, owing to the variety of subjects and the diversity of printing processes. Amongst the exhibits entered under "genre," was the champion picture of the exhibition, awarded a gold medal, won by Mr. D. Blount, of Great Britain. The title was "Innocence," and the process gum bichromate, the modelling of the head and shoulders of the child-subject being exceptionally good. At the year's exhibition the same gentleman won the gold medal with a different pose of the same child. Champion pictures become the property of the society, and the nucleus of a good art gallery is now in the society's possession. Several other masterpieces were shown in this

class by the same worker and exhibits of a high standard by members of the local society were entered in the list. In the class "seascapes" there was a capital show in all colours and processes; the prize was won by T. D. Leedham, New Zealand, for "When Evening's Twilight Gathers Round," a pleasing effect against the light, in a warm, brownish tone. Local workers also were exhibitors in this class and compared favourably. In Section III., non-competitive exhibits, there were five excellent studies by Mr. H. Ashworth, of South Australia. It is to be regretted that they were not entered in one of the competitive classes, as they must have scored to the honour of the society. Loan pictures were on view, and as they were by well-known photographers they received considerable attention. During the week the exhibition was visited by the patron, His Excellency George Le Hunte, K.C.M.G., etc. Every evening the prize lantern slides were shown. Short illustrated lectures, alternating with exhibitions of miscellaneous collections of slides, were given throughout the week and drew crowded houses. As some fifty slides were sent in for competition they formed an interesting lantern exhibit. The bronze medal (Section I.) was won by Mr. E. Atterton, and the silver one (Section II.) by Mr. Harold Hill, of Great Britain. The judge also selected and highly commended a slide entitled "Peaceful Evening," by Mr. Churchill Fisher, of Sydney. The judges were requested to highly commend any exhibits worthy of such commendation, the selection of pictures placed in this way proved interesting to the general public and served as an object lesson to exhibitors.—*South Australian Photographic Journal*.

SOUTHAMPTON CAMERA CLUB.

JANUARY 4TH.—Annual general meeting. The president, Mr. William Borrough Hill, in the chair. After the election of many new members the committee's report for 1903, and the financial statement, were submitted for adoption.

The former shows very satisfactory progress during the year, and it is gratifying to notice that the year closed with a membership of 140, to which were added many that evening. It is also highly pleasing to be able to record that the exhibition held from 11th to 19th December was a great success, both from a photographic and financial standpoint, the balance on that account being £35 17s. 9d., of which sum £5 were voted to the Mayor of Southampton, towards the Distress Fund. The work in the members' classes showed a marked improvement. The adoption of the report was proposed by the Hon. Secretary, Mr. S. G. Kimber, in a very lucid manner. He spoke of the amount of work done during the year, and the high position which the club occupied amongst the photographic societies, and assured the members that this could not have been done without very hard work and much sacrifice on the part of the hard-working committee with which he had so much pleasure in working. Whilst giving great praise to all, he felt it his duty to specially mention Messrs. G. Vivian, George R. Johnson, O'Connor, and Henley, who had constantly placed their services at the disposal of the club. He felt he must also mention the fact that but for the unbounded kindness of their president, who so generously placed their magnificent headquarters at their disposal, the club could not possibly be carried on so successfully. This was, he was pleased to see, specially mentioned in the report. The adoption was very ably seconded by Mr. Vialls, and carried with acclamation.

The adoption of the financial statement was proposed by the Hon. Treasurer, Mr. W. H. Trigg. This was of a highly satisfactory character, and showed a balance of £38 0s. 7d. at the bank. It was seconded by Mr. T. Weaver, and after a very useful discussion, carried unanimously.

Mr. William Borrough Hill was re-elected President, and in returning thanks said it gave him great pleasure to be at the head of so flourishing a society, and also to do all in his power to help it. He was pleased to see the suggestion to hand £5 of the exhibition profits to the Distress Fund, and would be pleased to augment the amount by another £2. The Vice-Presidents, Messrs. A. Horsley Hinton, G. T. Vivian, and Dr. Weston were also re-elected. Mr. S. G. Kimber was re-elected Hon. Secretary for the seventh time, and his election was

hailed with the utmost enthusiasm by all. He thanked them for their renewal of confidence.

Mr. W. H. Trigg was re-elected Hon. Treasurer, as was Mr. G. T. Vivian as Hon. Lanternist, and Mr. George R. Johnson as Hon. Reporter. The following were elected to serve as Committee for the ensuing year, viz.:—Messrs. A. E. Henley, M. O'Connor, A. Copeland, C. C. Cook, F. G. Ryder, H. W. Miles, G. Vials, T. M. Weaver, F. de Foubert, and Kay. The local and photographic press were accorded an enthusiastic vote of thanks for their kindness during the year.

News and Notes.

THE Croydon Camera Club have made arrangements for instruction classes to be held in the club rooms, 106, George-street, commencing end of January, open to members and ladies interested in photography. Particulars may be obtained from hon. secretary.

At the ordinary meeting of the Royal Photographic Society of Great Britain to be held at 66, Russell Square, on Tuesday, January 12th, 1904, at 8 p.m., Mr. B. H. Bentley, M.A., F.L.S., will read a paper entitled "Photographic Studies in the Biology of Flowers." The election of the scrutineers of the ballot will also take place.

MEASUREMENT of an Arc.—The Berlin correspondent of the "Standard," writing on Thursday, last week, says an estimate has just been submitted to the Foreign Office of the cost of the German share in the proposed Anglo-German measurement of an arc of the meridian in Africa. The total has been fixed at three hundred and fifty thousand marks. Negotiations with the English Government are still proceeding, and the German work in East Africa could not be commenced before 1906. The stretch of country selected for the measurement is situated between the Southern extremity of Lake Tanganyika and the Uganda Protectorate.

The Making of Worlds.—"The idea is seductive," says Miss Agnes M. Clerke, in "Knowledge," "that we see in every meteoric fire-streak a remnant of the process by which our world, and other worlds like or unlike it were formed. It is not a new idea. Chladni entertained it in 1794; and it has since from time to time been revived and rehabilitated with the aid of improved theoretical knowledge and a larger array of facts. Survivals are tempting to thought. It costs less effort to realise differences in degree than differences of kind. The enhanced activity of familiar operations is readily imagined; while perplexity is apt to shroud the results of modes of working strange to experience. Hence the presumption in favour of continuity; nor can it be said, even apart from our own mental inadequacy, that the presumption is other than legitimate. Nature is chary of her plans, lavish of her materials. Her aims are characterised by a majestic unity; but she takes little account (that we can see) of surplussage or wreckage. Now, it seems likely that meteorites represent one or the other of these two forms of waste stuff. They are analogous, apparently, either to the chips from shaped blocks, or to the dust and rubbish of their destruction. Let us consider what it is that we actually know about them. It cannot be said that the sources of our information are scanty. Fully one hundred millions are daily appropriated by the earth as she peacefully pursues her way. Their absorption leaves her unaffected. It produces no perceptible change in her internal economy, and makes no sensible addition to her mass. The hundred millions of small bodies taken up have, nevertheless, in Professor Langley's opinion, an aggregate weight of more than one hundred tons. And this increment is always going on. Yet its accumulated effect is evanescent by comparison with the enormous mass of our globe. That it was more considerable in past ages than it is at present, might be plausibly conjectured, but cannot reasonably be maintained. Geological deposits contain—unless by some rare exception—no recognisable meteoric ingredients. There is nothing to show that the earth was subject to a heavier bombardment from space during the Silurian era than in the twentieth century."

COLOURED Prints on Platona.—Prints on "Platona" paper can easily be toned to brown, plum, sepia, red-chalk, blue, and green in the following way. The prints are developed in accordance with the Ilford Platona formula in exactly the same way as for black and white. After development they should be fixed in at least three acid baths (the importance of this will be explained later), and well washed in running water, say, for half an hour. It is better to let the prints dry after the washing, as the toning seems to proceed more easily and quickly afterwards. One bath answers for the whole range of tones, from warm black to intense blue, running through the reds and terra-cottas, finally ending with a true red-chalk or brick-red, very suitable for head and figure studies. The toning bath does not keep well, and is better freshly made up a few minutes before use. Into a measuring glass pour five ounces of warm water, and into it put five or six grains (a grain or two more or less seems to have little effect) of uranum nitrate. When this has dissolved, add about five grains of sulphite of soda. This will cause the lemon-coloured solution to turn "milky." Having seen that the sulphite of soda is all dissolved, add very carefully, stirring all the time, drop by drop, one drachm of a 10 per cent. solution of potassium ferricyanide. Then with the same care add half a drachm of hydrochloric acid. This will cause the solution to become quite clear, but of a ruddy hue. Should it be cloudy, it must be thrown away and fresh prepared, as it will only discolour the prints if it is used. The reason for the "clouding" is that the ferricyanide solution added too quickly or not stirred. At this point it will be well to note the depth of printing required for the various colours. For terra-cotta, and red-chalk the prints should err on the side of underprinting. "What is termed a "weak" print proves most suitable for these shades, as the toning bath seems to have the effect of intensifying. Too much stress cannot be laid on the importance of roughly fixing the prints for these colours; if this is not done, the prints, muddy, stained prints are certain to result. The print is placed in the toning bath and carefully rocked; it quickly changes from black to brown, and from brown to terra-cotta, and from terra-cotta to red-chalk. The red-chalk tone will be reached in about five minutes from the time when the print is first placed in the bath. Chocolate tones are very easily obtained by using a bath which is already toned, say, six half-plates; but a little longer time must be allowed, on account of the weakness of the bath. Five ounces of solution should not tone more than six half-plate prints, as the solution then becomes muddy, and should be thrown away. Blue and green tones are got by taking a print, of any colour, which has been toned in the above bath, and placing it in a solution of sulphate of iron 1/2 oz., water 20 oz. In this the brown-toned print turns slowly to green, at which stage it should be removed if green is desired, and plunged into a bowl of acidulated water; but if blue is required the toning action should be continued until the print is of the desired tone. Next remove it to a bath of hydrochloric acid 1 oz., water 8 oz., and then wash in clean water. The tone given by the blue-toning process can be used for seascapes, etc., with charming effect. A bath which gives a brighter blue is made up of iron solution 1/2 oz., hydrochloric acid 1 drachm. This gives an intense blue all over the print. Should the worker wish to have his high lights pure white, all that is necessary is to go over the parts with a fine camel-hair brush charged with the ordinary oxalate developer. Should the prints be of an unsatisfactory colour—whether brown, red, or blue—simply place them in the oxalate developer, and they will return to their natural colour. The toned prints should not be washed more than a quarter of an hour, as the colour seems inclined to fade out in some cases. The three acid baths must be used because until all the iron is eliminated the prints get a slight blue tinge in the whites. This is pretty for some subjects, but unless it is specifically required use the three acid baths. Toning should be done by daylight, as it is somewhat difficult to judge the tone by artificial light. The idea that some people have that toning platona prints is a long and tedious operation will vanish when the toning bath here given is used. It may be relied on to tone to red-chalk, at the outside in five minutes, although three minutes is usually enough.—CLARENCE PONTING, in "Photographic Scraps."

Correspondence.

* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* We do not undertake responsibility for the opinions expressed by our correspondents.

FIRE INSURANCE.

To the Editors.

Gentlemen,—I have read with interest the letter inserted in your valuable paper of the 1st of this month, signed by Mr. Eady, and although I fully agree with him that it is desirable that a policy should be prepared in such a manner as to avoid, as far as possible, all chances of dispute should a loss occur; still, it must be borne in mind that it would be a very difficult thing for an insurance company to agree to pay, in the event of a loss, the amount for which a policy might have been taken out, without any further proofs that the goods claimed for were in the house at the time of the fire, and that the amount for which they were insured was reasonable, as in the latter case it would be necessary to have the articles valued by some expert, and the premiums charged would not be anything approaching the amount required for such valuation, and in the first case, even though the valuation had been supplied at the time the insurance was effected, there would be nothing to prevent the insured disposing of the property prior to the fire and still making a claim upon the company for goods which he had not in the house at the time of the loss, or for articles which may have been replaced by others of an inferior quality.

Mr. Eady points out that the chief causes of dispute arise through the difference of opinion between the insured and the company after a fire has occurred as to the value of the articles burnt. I would mention that the company I insure with recognises this point, and is prepared to sue policies agreeing with the insured what the value of the articles shall be in the event of a fire, provided he will supply the company with a catalogue of the articles valued by a suitable expert. This, in my opinion, is likely to reduce the possibility of a dispute to a minimum. The company, however, unfortunately restricts these policies to houses where the furniture is valued at not less than £500, as they put forward the plea, which certainly has considerable weight, that in the case of smaller houses where goods materially depreciate in value from wear and tear such articles are not replaced by new ones in the same proportion as in the case of houses containing furniture of greater value, and consequently it would be an incentive to a policy-holder not to take any special precautions against fire, as it would be to his advantage the goods were destroyed, seeing that they had materially deteriorated value.

Now, as regards the arbitration clause, it might certainly be desirable if all the companies excluded this from their policies, but it is necessary for an insured to carefully peruse his policy to see how the clause is worded. The clause on some of the companies' policies makes it a condition that the expenses of the arbitration shall be borne equally by the insured and the company, thus preventing an insured from going to arbitration, as the costs very frequently such arbitration would exceed the amount in dispute. Other companies, however, have a far more satisfactory clause, as it leaves the question of the costs of the arbitration to be decided by the arbitrators, as to who shall pay the same. Consequently, if an insured had a genuine cause of complaint, the entire costs of the arbitration would doubtless have to be paid by the company. On the other hand, the company would be protected from the insured putting forward a fictitious claim by the knowledge that the whole of the expenses might have to be borne by himself.

Lastly, I think it should be taken into consideration that, as a rule, the companies are somewhat compelled to be fairly honest in their settlements, seeing that there is such keen competition for the business that if a company was known to be acting otherwise it would prove most detrimental to that company's welfare.

I should be very pleased to give any information that may be asked from me as to the name of the company with whom I insure, and what procedure is necessary to obtain the most favourable policy.—

Yours truly,

LANG SIMS,
Member of the Committee, P.P.A.,

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

To the Editors.

Gentlemen,—I shall feel obliged if you will grant me space to say that we have published a little book containing the constitution, rules, list of members, and other particulars of this Association, and I shall be pleased to supply members with copies for distribution amongst their brother professional photographers, or to send a copy to any professional photographer who is not yet within our fold.

We have also had reprinted from "Judy" an extremely amusing skit on the advertisements of free portrait swindles, etc., a copy of which I shall be pleased to send to any professional photographer for display, as we think it might be effectively used to suggest to the public the true bearings of the Tarquerey and other frauds of the kind.—I am, etc.,

WM. GROVE, Hon. Secretary.

January 4, 1904.

DRY MOUNTING.

To the Editors.

Gentlemen,—I have just received a circular from the Adhesive Dry Mounting Co., stating they have secured the patent rights, etc., for Great Britain. Can you tell me in what way their process differs from one which appeared in the photo press many years ago, viz.:—To apply diachylon on the back of print, and when desirous of mounting the same lay the print on the mount in the position required and pass a warm flat iron over it?—I am, yours, etc.,

ENQUIRER.

January 5, 1904.

[We know nothing of the Adhesive Dry Mounting Company or of the process for which they have secured patent rights. Will our correspondent kindly send us a copy of the circular, and we will then give him our opinion of the process? In the Journal of June 26th, 1902, we described the Derepas system of dry mounting, which we understood was to be commercially exploited in this country.—Eds. B.J.P.]

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPH REGISTERED:—

J. Palmer Clarke, Central Hotel, Bury St. Edmunds. *Photograph of group of Otter and other Hounds.*

VULCAN.—We are much obliged for the reminder, of which we will take cognisance.

COLLOTYPE.—Of any photographic dealer; or direct of Messrs. Iliffe, St. Bride Street, London, E.C.

INQUIRER.—(1 and 2) You would be running the risk of an action for infringement. Don't play with edged tools. (3) The portrait lens.

H. KEELING.—(1) The volume most likely to suit your purpose is that of Dr. Moritz von Rohr on photographic lenses, of which, unfortunately no English translation exists. (2) The glasses may be obtained of Messrs. Zeiss. Better address their London agency.

COPPER TONING.—PHOTOPHIL says: "I should feel very much obliged by a reference to Mr. Ferguson's Copper Toning process, referred to at top of second column page 965 B.J.P., December

4th, 1903." In reply: The formula for copper toning is given on page 1,078 of the Almanac, and on the previous page there are several other formulae for toning bromide pictures.

BOOK WANTED.—SHUTTER asks: "Would you kindly tell me where I can get a good book on operating and studio work, with illustrations of posing, etc.; also price?" In reply: There are several good works on the subject, a list of which are given on pp. 974-5 of the Almanac, with their prices. Better consult that list. Any of the works can be had through the dealers or booksellers.

FAULTY LIGHTING.—PRINTER says: "I have been trying to photograph a la Rembrandt. There appears to me to be something wrong with the enclosed. I do not seem to have the control of my light properly; would be glad if you could give me some idea of the cause?" In reply: The lighting is certainly faulty. There is evidently too much top-light. Light the sitter more from the side with a strong direct light.

HYPD ELIMINATION.—A. J. STATHAM writes: "I have read Mr. Noton's letter relating his discovery of eliminating hypo from photographic prints in five minutes. Do you consider this method reliable, and is it adapted to plates and films? Why is it that some of our great photographic chemists have not recommended this process?" In reply: Theoretically the method should answer for films as well as prints. The best hypo eliminator in our experience is common H_2O . We know of no "great" photographic chemists in this country.

SPECKY PRINTS.—W. DOWNING writes: "Having experienced considerable trouble with spots on prints, I should like to ask advice on the subject. In the first place, I used water from a tank, and got them, next I tried water from off the main, and then used filter papers, with exactly the same results. The spots appear when washing prints before toning, sometimes twenty or thirty of them?" In reply: So far as one can judge from the example sent the spots seem to be due to the water. In the issue for December 11 there is an article on causes of spots; have you not read that?

PHOTOGRAPHY IN NEW YORK.—ANXIOUS writes: "As I am desirous of going to New York, will you kindly inform me (1) if there are any good openings in the photographic line, and if, with three years' experience in London firms, I should stand a chance of getting a berth? (2) Also, do you know of any American photographic papers similar to the B.J.P., and, if so, are there any sold about London?" In reply: (1) Better stay where you are. (2) A list is given in our Almanac. No doubt the Secretary of the Royal Photographic Society, 66, Russell Square, London, W.C., would allow you to see them.

DEVELOPER.—AMATEUR says: (1) "I have just made up the following pyro-soda developer for Paget plates:—No. 1—Pyrogalllic acid, 4 oz.; sulphuric acid, 5 drops; water to make, 20 ozs. No. 2—Soda carbonate, 2 ozs.; soda sulphite, 2 ozs.; water to make, 20 ozs. Will you kindly inform me whether the above solution should be further diluted, and, if so, how much water should be added? (2) How much solution is necessary to develop one quarter-plate? (3) How long will the solution keep in corked bottles or stoppered bottles?" In reply: (1) The solution should not be diluted. (2) Sufficient to well cover the plate when in the dish you use. (3) Several weeks if the solutions are kept separate.

COPYRIGHT.—W. U. writes: "I gave our local editor a copy for use in paper, and charged him 10s. 6d., sending in my account made out (for reproduction in paper). Now he has sold his block to another party, who is making use of it for post-card selling, which has stopped all my sale for the original copies, and which I was having a good sale for. Now I thought if I copyrighted this at once, and after it is entered at Stationers' Hall, I should be perfectly within my rights to stop the sale of these cards, is this right?" In reply: This is a question we cannot answer with certainty, but we think it probable that you can stop the sale. You should have made the picture copyright before you sold the right to reproduce, and also have stipulated that the

picture should only be reproduced in the paper. We should advise you to consult a solicitor well versed in copyright law.

COLOURING PHOTOGRAPHS.—J. J. S. asks: (1) "Will you kindly give me the title of a good work on miniature painting, tinting photographs, and possibly including finishing enlargements? This is a book published by a firm of artists' colourmen in London." "The Art of Miniature Painting and Colouring Photographs" but it was published a great many years ago, and refers only to colouring silver prints. No doubt there is something much more up to date. (2) Also, if the question is admissible, is there any method of making an enlargement from a photograph on paper or canvas except the plan of dividing into squares, the principle used by engravers?" In reply: (1) The work referred to is published by Newman and Co., Soho Square. "The Art of Photographic Painting," by A. H. Bool, is a more modern work. (2) Enlargements are made on paper by the bromide process, and on paper or canvas by the carbon process.

COPYING-LENS.—C. MARSHALL asks: "(1) May I have your advice the following: I wish to make a lantern slide from some printed matter, which is done in blue ink on white paper, but not very clean paper. I have tried with ordinary plates but cannot get density, and at the same time contrast in the negative, the blue printed matter seems to have nearly the same effect on the plate as the white paper. How should I proceed with above to get a good negative? (2) I understand that a lens with a large number of open or reflecting surfaces is slower than it would be if it could be made solid with only two surfaces. If that is so, I am right in thinking that in using a colour screen or filter close to the lens, I am adding two more surfaces to the lens, which will cause a loss of light, which ought to be allowed for, as well as the loss caused by the colour of filter." In reply: (1) This is somewhat difficult subject that you have to deal with. We should advise you to try orthochromatic plates with a yellow screen. (2) This is, theoretically, correct, but it may be neglected in practice, as the loss of light is so very little.

LIGHTING STUDIO.—CONSTANT READER says: "(1) I am thinking of opening a studio near here, but am in some difficulty about lighting, as I can only get top-light. Is there any kind of reflector I can use to give the desired effect; also, what glass would you advise me to use. I am sending you rough sketch so as to give you some idea of the position and size of building. Would covering the side-walls with some white material help, by using a large mirror as reflector help matters? (2) Do you think I could take sitters satisfactorily at night by gas light, advertised, or would you recommend electric light; if so, could you kindly advise on any good outfit?" In reply: (1) Good portraits can be taken in such a studio as is shown in sketch, but, as it is so short, it will be somewhat difficult work. Better have clear glass, and the side-walls of a light colour. White screens to use as reflectors will be necessary. (2) We do not know the light mentioned. The electric light is preferable to gas for portraiture. See the advertisement Messrs. Adamson in the advertising columns of the Journal.

* * * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Metropolitan The well-known firm of metallurgists in Hatton Garden, Messrs. Johnson, Matthey and Co., have, for a quarter of a century past, dealt with large quantities of ore in the extraction of uranium, and the waste has been thrown away, and now probably is buried in countless dustheaps deposited in various parts of London. It is credibly stated that this waste contains appreciable quantities of radium, and as this element, on account of the embargo laid upon the export from Austria of the pitch-blende, from which it has been extracted, is worth something like a quarter of a million sovereigns a pound; it is not difficult to imagine the heart archings consequent upon the discovery of the value of the lost uranium waste. That a newspaper has hidden a thousand pounds just below the surface of the soil somewhere in London, to become the possession of the finder, seems a mere trifle compared with the radium store of wealth beyond the dreams of avarice. We are afraid, however, that the thousand pounds' worth of hidden discs are more likely to be found than the priceless hoard of radium.

Radium at The people of Bath have likewise suffered a radium disappointment. London's store is lost, that of Bath is found; but when found it is discovered to be in such small quantities

as not to pay for extraction. We have learnt how radium converts itself, or a portion of itself, into helium, and as helium has been found in gas issuing from the Bath waters, it was natural to suppose that radium might be there or thereabouts. The Hon. R. J. Strutt, son of Lord Rayleigh, has examined the deposits left by the waters of the hot springs, and has been able to discover the presence of radium; but, unfortunately for the newly-raised hopes of the inhabitants of this ancient city, the cost of extraction would exceed the value of the radium that could be extracted. It is probable that whatever eventually may be found to be the value of this marvel of modern science in photographic practice, so keen is the search for it that sooner or later fresh sources of supply will be discovered, and the latest news in this direction is that we may possibly find our own country to be in possession of the necessary deposits of ore. According to the "Cornish Guardian" we may have it from Coombe Farm, near St. Stephen, in Bramwell; for some examples of ore have been sent to "an eminent scientist on the Continent" who was greatly struck by their sterling value, and since then the surveyors have been making further tests. The Cornish mines have for years past been known to hold uranium which, as our readers are aware, has been the primary source of radium so far.

Photographs in We have received from Germany a considerable amount of literature descriptive of a process of photography in natural colours, which is, to say the least of it, interesting and somewhat curious. The basis of the process is the well-known carbon or pigment process, and paper is prepared with three films, the top containing a blue pigment, the middle one a green, and the lowest a red pigment. This tissue is exposed under an ordinary negative, and then developed in the ordinary way, the result being a print in colours. The explanation of the process is that, assuming we have taken a landscape, the blue sky would act most, and give, therefore, most density in the negative; therefore the least light would reach the compound carbon tissue, so that the underlying green and red films would dissolve away and leave only the blue. The green of the trees would act less, give less density, and allow more light to pass; hence the blue and green films would be rendered insoluble, and the red would wash away, leaving green. Red objects would act least or not at all, and hence the light would pass through all three films, and the red be reproduced. Thus far the official description. It is obvious that there are one or two very serious practical and theoretical objections, which personally we do not see any way out of. In the first place, no red and green pigments can make a yellow; hence a fourth film of yellow would have to be

provided, or this would have to take the place of the green film. Absolute opacity of each individual film is also a sine qua non, or otherwise there would be no pure colour, but only smutty or secondary tints, because, for instance, if the red film were not opaque, the green underlying it would show through. Again, how is white to be reproduced, unless absolute and impenetrable opacity is obtained in the negative? Moreover, it is obvious that correct exposure would be essential, and if a colour-sensitive plate were used, the composition of the positive film would have to be altered. On paper the process reads well, but it will, we are afraid, join the many other processes which have been advanced and found useless.

* * *

Patent Applications in 1903.

The weekly journal issued by the Patent Office shows that the number of patents applied for during the year just ended amounted to no less than 28,818. Our "Patent News" column week by week has shown that photography contributed very liberally towards the above number. For example, no less than forty-five applications for patents in connection with photography were made during the month of December alone. It is not a little interesting to compare the numbers of patents being applied for relating directly to photography at the present time, when it would seem there was little scope left for real invention, and the numbers in the past, when new discoveries and fresh inventions were being continually made. If we take the five years, 1849-54, during which years great improvements were made both in connection with processes and apparatus, including the invention of the wet-collodion process, which, by the way, was not patented, we find that only 32 patents all told were applied for in the five years. In the month of December last, as we have just said, there were 45 applications relating to photography. What a contrast! Seeing this great difference between past and present, one is rather inclined to speculate as to whether the larger proportion of the patents now taken in connection with photography are really valid should they have to be contested in the Law Courts. We have a strong opinion on the subject ourselves. Another point for speculation is what proportion of the photographic patents repay the patentees the costs for the stamps, small though they be. It is surprising that so many persons, when they fancy they have discovered or invented something new, rush to the Patent Office without considering whether the patent when obtained is of any commercial value whatever, valid though it may be. Although so many patents are annually applied for and provisional protection granted, it does not follow that anything like the number will be completed, for they certainly will not. A very large proportion of them will be abandoned at the initial stage, and the complete specification never lodged. At one time provisional specifications used to be published, even if the patent were not completed; now they are not, and one has no means of learning any details of what the provisional protection was granted for.

* * *

Adulterated Chemicals.

A case of considerable interest to users of the "pyro-soda" developer was dealt with, under the Merchandise Marks Act, at the Mansion House Police-court on Friday last. A firm were prosecuted for selling with a false trade description goods called soda crystals. Soda crystals, it may be mentioned, are what is known as the washing soda of commerce, which is carbonate of soda with the water of crystallisation. In the manufacture of the soda crystals it was explained to the court that in order to make the crystals less sticky, so that

they could be crushed and put into the drying machine more conveniently, a very small percentage of sulphate of soda is added. This addition in honest manufacture never exceeded 2 per cent., and in some cases was even less than that. A practice has grown up of late, it was stated, of adulterating soda crystals—carbonate of soda—with sulphate of soda—Glauber's salt. The difference in the price of the two salts is great, the price of soda crystals being some £4 10s. a ton, while the sulphate of soda is but £1 16s. per ton. An analysis showed that the stuff sold by the defendants, instead of containing 98 or 99 per cent. of carbonate of soda, contained only 9 or 10 per cent. of it and not less than 91 per cent. of Glauber's salt in the form of crystals. In the end, as the defendants had pleaded guilty, the Lord Mayor, as the prosecution did not press for a heavy penalty, only imposed a penalty of £20 on each of the six summonses—£30 in all. Now, many photographers who use pyro-soda as a developer use common washing soda; indeed, some plate makers in their formulae give common washing soda as the material to employ, and this is usually obtained from the nearest oilshop. Hence, it is easy to conceive, if a photographer were supplied with "washing soda," such as that referred to above, what the result would be. If he were one who habitually used the pyro-soda developer he would at once know what was wrong. Not so, however, in the case of one used to pyro-ammonia, and who tried the soda developer for, perhaps, the first time: he would at once condemn it as being useless. In the case of a beginner in photography being supplied with such a sample of washing soda, one can well imagine what his trouble would be and his difficulty of getting out of it, or, at least, ascertaining the cause. Washing soda containing 90 per cent. or over, of sulphate of soda, instead of acting as an accelerator in the developer, would practically act as a retarder. Seeing from the evidence adduced at the Mansion House Police-court last week the extent to which soda crystals—the washing soda of the oilshop—are often adulterated, we should advise that only the pure carbonate of soda as supplied by the dealers in photographic materials be employed, and that the oilshop article—for fear of it having been sophisticated by its manufacturers—be eschewed.

* * *

The Iris Diaphragm.

The iris diaphragm no doubt appears to so many photographers of the present day as such an essential and constituent part of a lens that they will scarcely understand that its general employment is, in comparison, quite a modern addition. The old-time photographer was content with a stop placed in front of his lens—a cumbrous short tube, with a partially closed end, with the maximum aperture, smaller diaphragms being flat sheets of metal, pierced with circular openings of diminishing size, and kept in situ by means of the tube-stop pushed against them. Then came a valuable improvement in the portrait type of lens, the diaphragm being inserted in the lens tube, between the anterior and posterior combinations, by means of a bulky arrangement like a shallow box, which again was displaced in favour of the arrangement still in use at the present day—a metal saw-cut in the tube, extending almost to half-way through and protected from the entry of light by two annuli securely fastened interiorly on each side of the slit, and between which the thin metal diaphragm is made to slide. The arrangement, called after its inventor, being known to this day as the Waterhouse diaphragm. An innovation of great convenience with lenses worked at an aperture that would now be considered small was familiarised in this country by the Portable Symmetrical, made by Ross.

the set of Waterhouse stops being replaced by a single revolving disc of metal, pierced with the requisite apertures, and so arranged that as the disc was turned, each aperture was brought in succession exactly in the axis of the lens. This "wheel diaphragm" has been largely displaced by the "iris diaphragm" with regard to the invention of which there may be some controversy. A paragraph in "Nature" of December 31st last, referring to the death of Mr. John Henry Brown, of Hove, says his death "recalls the little-known fact that, as the inventor of the iris diaphragm, he has laid the scientific world under a considerable obligation." A communication from Dr. Hollis of that town is quoted, and speaks of Mr. Brown taking his home-made model to Smith and Beck, the well-known firm of opticians in Cornhill "in the early 'seventies." "Great minds think alike," and here appears to be an instance. We do not doubt for an instant that Mr. Brown's invention was original (we are not told whether it referred to microscopic or photographic lenses, probably the former, as we believe the Messrs. Beck did not manufacture photographic lenses at that time), but that the iris diaphragm had been in existence some years before the time stated is certain. We cannot give, at the moment, a reference to any printed description, but an old and well-known contributor informs us that somewhere about 1865 he was shown by a Liverpool photographer named Vogel a foreign made portrait lens with an iris diaphragm. It would be interesting to ascertain the age and genesis of that lens.

RADIO ACTIVITY.

It is highly probable that many mysterious appearances upon photographic plates which have perplexed many workers will now be satisfactorily accounted for. Again and again have we had inquiries as to the meaning of certain markings which have come unbidden upon the sensitive surface, and too often, we fear, has our surmise as to their origin given little satisfaction to the querist. But now that radio-activity is recognised as such a common quality, and is being investigated by so many students of science, we may hope that many occurrences, for which no good explanation has been forthcoming, will have light thrown upon them.

Nearly thirty years ago, when Mr. Kennett was selling to a few amateurs gelatine emulsion in the form of "pellicle," with which they could coat their own plates, he warned his customers not to keep the unexposed plates in pine boxes, unless the interior of the receptacles were first coated with spirit varnish, for there was some emanation from the wood which spoilt them. Long after this, when the prejudice of the professionals had been overcome, and gelatine plates became necessary to all workers, it was discovered by many that a plate left in a dark back for any long time would become impressed with a complete picture of the wooden shutter in front of it, and of the leather hinge with which it was furnished. We may surely regard these as among the first observations of radio-activity, although at that date the term had not been invented.

But we can go back still further to some experiments recorded by M. Niépce de St. Victor,* which, although not of exactly the same kind, have a distinct bearing upon the subject. He had, of course, no dry plates to play with, and the fact that he obtained evidence of action upon

slow chloride of silver paper makes his experiments the more remarkable. They were devoted almost entirely to the light-giving power of different bodies after they have been insolated—i.e., exposed for some time to the action of the sunlight.

First, he records that if an engraving be exposed for some time to sunlight, and afterwards placed in the dark in contact with chloride paper, an impression of the picture is produced in a very short time on the paper. After this he tried such different substances as white porcelain with black figures, linen, wood, marble, cardboard, etc., and every time he succeeded in getting an image on the paper. He also succeeded in "bottling up light" as he expressed it—that is to say, he insolated a substance, shut it up in a dark tube, sealed up the tube for a week or more, and then, in the dark, placed sensitive paper against its orifice, with the result that he obtained an impression of the opening of the tube in a very short time. It is interesting to note that the substance insolated was a sheet of cardboard, which had been treated with a solution of tartaric acid, or a salt of uranium. This cardboard was rolled up so as to form a lining for the tin tube.

It will be recalled to the memory here that Becquerel, in his far more recent experiments on the radio-activity of the uranium salts, first exposed them to light, and attributed their marking of a photographic plate to this insolation. He subsequently found that uranium needed no such preliminary treatment, but would affect a dry plate, although the salt employed had been made in darkness, and kept from all light access. It is evident that if M. Niépce had had gelatine plates to experiment with he would have anticipated Becquerel in some of the results at which he arrived, with regard to uranium. This is a very interesting point, because the uranium observations led the way to the discovery of radium.

All these early experiments and observations had been half forgotten when, six years ago, just about the time that radium was being recognised as a new element, Dr. W. J. Russell gave to the world the results of a series of remarkable observations on "the action exerted by certain metals and other substances on the photographic plate." It may be thought by those with good memories that a paper only six years old is too familiar a thing for discussion; but in this age of hurry, when one object of interest eclipses another rapidly, there must be many who have forgotten Dr. Russell's experiments and many newcomers into the photographic arena who have never heard of them. To us they seem to possess a new interest in the light of recent and current discoveries.

Dr. Russell used for his experiments both plates and bromide paper, but preferred plates of the rapid kind, because the paper was naturally more sluggish in its action, and he obtained evidence of what we may now call radio-activity from a number of different things, both organic and inorganic. Possibly he was not aware of the former experiments of Niépce, to which we have referred; at any rate, he does not seem to have mentioned them, as he probably would have done if he had known of them.

He made experiments with many metals, placing each, sometimes in actual contact with, and sometimes separated from, the gelatine plate, in darkness for a period ranging from 19 to 118 hours, afterwards developing the plate in the usual manner. He found that magnesium was the most active of those he tried, and he placed the others approximately in the following order:—cadmium, zinc, nickel, aluminium, lead, bismuth, tin, cobalt, antimony. He found, too, that certain alloys were exceedingly active, notably pewter and fusible metal, while, strange to say,

* *Comptes-Rendus*. 1857, et seq.

others, like German silver and brass, are inactive, while aluminium-bronze is only slightly active.

The metal experimented with must have a bright surface, and in employing zinc, Dr. Russell polished it up with emery-cloth or glass-paper in order to bring it into condition. If left in the air for a day or two, it became quite inactive, and the same result was brought about by washing its surface with dilute sulphuric acid. The faintest markings on the metal plate, even the scratches caused by the emery-cloth on the zinc, were faithfully reproduced on the gelatine plate. If the zinc plates were amalgamated with mercury, the action was much intensified, and Dr. Russell was able to show a picture of a skeleton leaf produced in this way by contact in darkness of only two minutes' duration, the leaf being placed between the metal and the gelatine surface.

There were many other interesting experiments made with metals, but we cannot afford space to refer to them. One observation, however, seems to have such a likeness to what we have all been reading lately of the power of radium to transfer its radio-active properties to bodies which were previously quite inert, that we must allude to it. Dr. Russell found that pure alcohol, ether, and chloroform had no effect whatever upon the plate, but that if any one of these liquids were shaken up with some turnings of bright zinc, and were allowed to stand with the zinc immersed for about four days, and the metal turnings were then removed, and the liquid filtered, it would become active. Even if distilled, the volatile fluid so treated with metallic turnings would not altogether lose its property of affecting the gelatine surface. Several liquids could be made active in this way, but others, such as benzene, and petroleum spirit, were quite inert.

Quite as curious were the experiments made with various organic solids, and perhaps the most interesting to photographers were those recorded of printing-ink. Many amateur workers have found to their dismay that an exposed plate wrapped in newspaper, will, when developed, exhibit a very perfect reproduction of the type matter. This is due to the activity of the linseed-oil and of the turpentine with which the ink is prepared. The terpenes are all remarkably active, and so are most of the vegetable oils—with the exception of olive oil, which is almost inactive. Copal, in the form of varnish, is very active; whilst gum arabic is inert.

We are reminded of the behaviour of the X-rays when we read that the emanation from the various bodies and liquids tested by Dr. Russell will pass through paper, celluloid, collodion, gutta-percha, gold-beaters' skin, vegetable and animal parchment, besides a number of other things.

With regard to the action of wood, either in plate-boxes or in dark backs, upon gelatine plates, Dr. Russell's experiments show that most kinds of wood will leave a record if left for even a short time in contact with the plate. And it does not seem to matter much if the wood be new or old. One specimen he showed in which all the grain markings were transferred to a plate from a block of oak, which had been kept in a dry room for about 100 years.

Details of all Dr. Russell's experiments will be found recorded in the proceedings of the Royal Society, and in the light of recent events they will be referred to with renewed interest by many. Whatever be the ultimate explanation of the effects recorded, it must be admitted by all that the gelatine plate is a most sensitive detector of radio-activity—as sensitive perhaps in this way as the telephone has proved to be in the recognition of currents of electricity which would, without its aid, have quite escaped observation.

THE PYRO AND PYRO-SODA DEVELOPER.

A CORRESPONDENT has asked, with regard to our statement that "it is not difficult to remove green fog without injuring the quality of the negative," "how to do it?" We are inclined to reply by an hibernicism, and say, "prevention;" do not use a plate that gives green fog, or, having stock of such plates, do not use ammonia. But as we know many workers are wedded to pyro-ammonia, we may say that a very weak solution—about one per cent. of ferricyanide of potassium applied with a pledget of cotton wool will work wonders; if the stain be very pronounced, it will be desirable to mix a little hypo solution with the ferricyanide, to make a dilute Howard-Farmer solution in fact, taking great care not to hurry the matter by using too strong a solution.

Notwithstanding the well-known drawbacks to pyro as a developer, there is no doubt that a very strong body of workers prefer it and with ammonia, and especially is this the case where lantern slides are in question. We believe it to be the case that the most expert slide-makers in the Liverpool Amateur Society—a society which is pre-eminently successful in lantern work generally—pin their faith to pyro-ammonia as a developer, with magnesium light as an illuminant. Although pyrogallol and its decompositions have been studied by several eminent chemists, there is much that is obscure with regard to the exact chemical nature of its products when applied to an exposed plate. The image consists of a something beyond pure silver, and is dual in character, being partly composed of minute opaque grains of metallic silver, and partly a pyro-decomposition product in the nature of a transparent stain, and it is supposed that it is this latter substance that gives the particular quality that distinguishes a pyro developed negative, and which certainly gives a peculiar richness to lantern slides difficult to mistake by any of the more modern developers. There is another point with regard to the obscure decompositions of pyro which may be mentioned at this stage. It is sometimes asked why pyro should not be made in one-solution form like most of the "quick-starting" developers may be compounded. But, even if kept in well-filled bottles so as to exclude as much air action as possible, the plan is impracticable for a very simple reason. Pyro developers, from the moment they are made, are liable to a change of character, even if atmospheric air be entirely excluded and the colour remain unchanged. A developer mixed, and at once put into a bottle so as to fill it up to the stopper, will, at the end of twenty-four hours, and though unchanged in colour, take a much longer time to develop a plate than it does when first mixed. It acts like a once-used developer, and gradually becomes valueless. There is, however, one exception to this rule, and that is when the "pinnakol salt N" is made to take the place of the ordinary alkali. A one-solution developer may be so made which will keep in good condition for months, and even when greatly discoloured, will be found to give unstained negatives.

We now pass on to the one great objection to pyro as a developer—its excessive readiness to stain the fingers. We do believe that, were it not for this especial characteristic, pyro would be used to the virtual exclusion of every other developing agent. With care it is possible to use it and have but slight stains produced; but it is next to impossible to avoid getting the nails, especially round their base, thoroughly browned, almost as though dipped in iodine solution. Of course, much, if not all, of this latter stain may be avoided by slightly smearing the nails and finger-ends with vaseline, and so repelling the pyro solution; but as so much preparation and waste

of time is involved in doing this, few care to go to so much trouble. In actual practice the best plan to adopt to avoid this staining is the simple one of continually dipping the fingers in clean water before and after contact with the developer, and, as a matter of comfort, occasionally wiping them on a towel. There is a certain amount of absorption or penetration of the cuticle by the pyro solution, and if the hands be saturated, as it were, with water previous to immersion, it is evident that less pyro would be absorbed than would be the case with a perfectly dry skin, and in practice this theoretical idea is found to work. Indeed, it is surprising how many plates can be handled and developed with little or no finger-staining when this simple precaution is taken. As to the laving the fingers with water for a moment or two after pyro solution has touched them, it is obviously desirable, even as a matter of personal comfort, for the alkali alone of the developer has a disagreeable action on the skin when it is subjected to it for any long time. Here, again, we have a preventive, rather than a curative, process. As to curing—i.e., getting rid of the stains with or without the above precautionary measures being taken, there have been scores of remedies propounded; but the simplest and most efficient is the use of solution of bleaching powder—the so-called “chloride of lime”; but to obtain its utmost efficiency, a little hydrochloric acid should be added; the efficiency of action is then greatly exalted. Referring again to the least known addition to pyro for developing purposes, the pinnakol salt, we may say that it is stated that, with its use, staining of the fingers does not take place. Should this prove correct, we predict a great popularity for this at present little-known addition to *materia photographica*. We will conclude by an amplification of our formula for a pyro-soda developer, by giving details for compounding stock solutions. The pyro solution, usually termed No. 1, may be made by dissolving an ounce of pyro in 20 per cent. of sulphite of soda, adding about a drachm of citric acid, and making the bulk up to a pint. This gives a 5 per cent. solution. The alkali solution (No. 2) may conveniently be made by the Winchester quart at a time, and is practically permanent in well-stoppered bottles. This quantity, when made as we will explain, is only a little more than is required for an ounce of pyro. Half a pound each of carbonate of soda crystals and of sulphite of soda, are dissolved (most conveniently in hot water), and the bottle filled up to the shoulder, the measure being then at a rough calculation about 80 ounces, thus giving a solution with 10 per cent. of alkali. If, through hardness of the water, a precipitate occurs, it will fall to the bottom in about a day, and filtering be avoided. To compound a developer (just before use), the pyro and carbonate of soda solutions should be mixed in the proportion of 1 and 3, and then water equal in bulk to the combined solutions added. Bromide may be added or not, according to the plate in use. This will give a developer with 3 grains of pyro, 18 grains of soda, and 30 grains of sulphite to the ounce—a useful, workable, easily-mixed formula, applicable to a wide range of plates.

By the death of Mr. Joseph Bell, which occurred on the 5th inst., at Liverpool, there has passed away the head of two well-known Liverpool firms. As the proprietor of the business of Bell and Son, french polishers, and that of Brown, Barnes, and Bell, photographers, Bold Street, the late Mr. Bell enjoyed the esteem of a wide circle of friends and patrons, the collection of photographs at the Bold Street house embracing nearly all the leading people of Liverpool and district for over a generation.—“Liverpool Mercury.”

MAINLY ABOUT FOLK.

By THE AMATEUR OPTICIAN.

It is pleasant to be able to report a fair amount of business at this season of the year. I cannot say anything about the Christmas card as such, but I do know that the amateur goes in more largely than ever for prints from his own negatives, which he mounts, for the most part, in a very tasteful manner, aided in this direction by the mount manufacturers, of course. It is not possible to ignore some of these productions—the very evident artistic ability displayed, skilfully and carefully-chosen subjects admirably suited to the purpose, in size, form, and colour, these appear to be the rule. It is curious to note how often these little photographic bits appear from altogether unexpected quarters. I have sold plates and paper for some years to an amateur without by any chance ever seeing a sample of his work; nobody knows anything about him; he belongs to no society; and whether he is an expert or a mere waster is a big uncertainty; when suddenly he turns up with a few negatives for enlargement, and I see something which gives unalloyed pleasure. I begin now to look out at Christmas time for surprises of this kind, for there are many modest, silent, unassuming young fellows about with cameras who have a real genius for the art.

Some time ago, in these notes, I mentioned the fact that dry batteries for electric bells, etc., can be rejuvenated by making perforations in the zinc casing, and soaking in a solution of chloride of ammonium or zinc. The matter is referred to again because it is interesting to mention the fact that a set of these batteries, treated as described five months ago, at time of writing, are working vigorously, and show not the smallest sign of giving out. By the way, a big firm of cash chemists are selling thousands of those pocket flash-lamps which are useful, *inter alia*, not only to the man who has been working late and finds it difficult to discover the number of his house and the exact spot in which to insert his latch-key, but also to the photographer in search of a novelty. My customers tell me they use these for a variety of purposes; one as a convenient illuminant in exposing lantern plates; another, when photographing an engineering model, found one of these lamps very useful to throw a beam of light over the dark portions of the same during the exposure of the plate; while a third, having tied up his lamp in a piece of red tissue paper, by the illumination thus provided developed some plates.

Mr. Martin Duncan's article on X-rays serves a very useful purpose; at the same time, you may talk about the delights of radiography, and the experimental interests of the electrical phenomena of Hertz rays, and wireless telegraphy, etc., till all is cerulean, but it is only on very rare occasions that you will find the client willing to part with £40 or £50, which would be about the price of a set of apparatus ready-made, suitable for experiment and demonstration. There are plenty of amateurs who enthuse on such matters provided they are not put to any personal inconvenience or called upon to pay for the pleasure. The enthusiasm which impels a man to sacrifice his “bike,” limit his wardrobe, or at the least weed out his collection of apparatus, which in itself is a painful process, in order to find the requisite specie for further outlay, is, unfortunately, rare. In times “lang syne” I pinched myself all round in order to be able to own a particular set of lenses; a time when, as now, for that matter, you could spend £50 on the optical part of your apparatus, and not see very much for your money. But certain lenses by certain makers were the rule in our particular society, and there was also the requisite enthusiasm, and the encouraging results. But for pure fascina-

tion and the impelling influence which makes a man do odd things in order to get on with his hobby, give me electrical work, frictional apparatus and coil-making (in itself an absorbing pursuit), and the class of work which keeps one in the wake, no matter how far behind, of Professor Oliver Lodge, Testa, and Marconi. What about that grand old amateur, James Bowman Lindsay? It is amazing what he accomplished between, say, the years 1830 and 1860, on a beggarly salary of £50 a year! We read that "all his life he must have pinched himself to the utmost limits in order to purchase materials for his numerous experiments. He worked and worked alone, on the borders of starvation, in one room—all he could afford." Experiments in electric lighting, wireless telegraphy, and, doubtless, all the work incidental to the period when the "Rhumkorff coil" was comparatively new.

"Some of Lindsay's experiments" (I read) "were made in the presence of two friends, one of whom says that Lindsay would station them on one side of the Tay, requesting them to watch carefully the magnetic needle he had placed in position, and to note how it moved. He would then insert his plates in the water on their side of the river, and crossing over to the opposite side, would complete his arrangements. His battery, containing twenty-four Bunsen cells, would be set in action. Later on Lindsay would return and question them eagerly as to the behaviour of the needle. The different movements to the right and left would be noted, and, on comparing them with the messages he had sent from the other side he was perfectly satisfied he had accomplished telegraphy without continuous wires. He would then return to his little room as happy as possible. It is comforting to know that the studious Lindsay, with all his poverty, got some satisfaction and joy in this life. Nowadays we can purchase batteries and wire, and all electrical appliances, at a moderate cost, and every detail ready for immediate service. Not so in Lindsay's day. He had to make up his cells, and possibly to coat and otherwise insulate his wires." He had to make his own intensity coils, one of which, we read, measured $4\frac{1}{2}$ ft. long, and contained five miles of wire. The author continues: "Think of it! Think of the cost, and where the money was to come from. Think of the patience of the man with primitive and limited appliances. The modern experimenter in electricity has no difficulties compared with those combated by Lindsay. Besides, in Lindsay's case, more wire, more acids, more metals, meant less food, less new clothes, less comforts of all kinds."

I have just overhauled a set of three whole-plate double dark slides which, last summer, performed in an erratic way, that is to say, one or other on occasions, when presumably the light was particularly strong, turned out a plate "foggy" here and there, by reason of entrance of the light at some part which certainly should have been secure. Glancing along the edges where the two halves of the slide come together, it was clear that at certain places there was space sufficient to allow of the entrance of a piece of thin note-paper. The slides were doctored up as follows:—Firstly, mark with a pencil the parts where the slides were mechanically imperfect; next make a little thin glue of the best quality, to which should be added a few grains of powdered bichromate of potash; apply to the parts marked, the slide being open upon the bench, a thin coating of the hot glue, and before this has time to set, sift over it some fine sawdust, which, settling down and drying hard, fills up the uneven surface. By means of a rasp and sandpaper bring the surface up level or otherwise make a perfect fit with the opposing half.

The uncertainty with regard to the letter "h" is always amusing. A smart young man invariably asks for hamidol or hi-konogen; another usually calls "hypo" "ipo"! I have, I may say, a reputation amongst a circle of friends as an authority upon minor ailments and remedies. It is, therefore, a very ordinary circumstance, when packing up some dry plates, to have to listen to various details concerning the state of health of Tom, Dick, or Harry. An exceedingly pleasant lady customer of mine, who has a habit now and then of misplacing the "h," was in the other day, and, when I inquired after little Mary, she said, "Not at all well, Mr. O., just now, she has been over-heating herself." This was a bit of a puzzle. Did she mean over-eating? I concluded so, and sympathised in the usual manner. I have one "igh and 'orty" customer, who generally asks for para-amid-o-phenol, which reminds me of a certain pharmacist in the North, a small man with a big side on him. The gentleman was opening a debate on "Cocaine," which he pronounced—as of course he had a perfect right to do—"Ko-ka-i-nec." The constant repetition of the word in the course of a discussion covering an hour or so, was a weariness to the flesh, the only relieving feature being that the gentleman now and then called it "Ko-ka-hi-ne"! At such times a touch of joy would pass over the faces of the younger of the members present, and much would be forgiven. In my apprenticeship days a colleague distinguished himself in a similar way. He was a member of the local Amateur Dramatic Society, and had been cast for a part—two lines—in the production then being rehearsed. He was up early and late, practising his lines before the glass. I cannot remember the exact words, but he had to walk on as a footman, and announce the arrival of something or other with an "h" to it, or rather, to be exact, a word to which an aspirate can easily be applied. We, who knew our friend's little failing, watched the performance on the great night with consuming interest. The fatal moment arrived. The side door O.P., or wherever it is, opened, and in stalked, with the "hair of a hemperor," our amateur. All the weeks of preparation had gone for nothing: "My lord, Sir Hedward waits below," brought a part of the house down with screams of delight, oft repeated and never forgotten.

EVERYONE who has seen pretty Miss Marie Studholme, of the Gaiety Theatre, and everyone who has seen her portraits (says a contemporary) have been compelled to admire her pretty teeth. Someone has admired them so much that they were used in an advertisement, and now someone has apologised for so doing, the apology appearing in the "Standard" as follows:—"I do hereby humbly and sincerely apologise to Miss Marie Studholme for having wrongfully and without her authority used her portrait for advertising purposes, in a manner calculated to induce persons to erroneously believe that certain of her front teeth are missing and have been replaced by false ones, and I admit that the advertisement so issued by me is libellous, and I authorise the said Marie Studholme to insert this apology, at my expense, in such public newspaper or newspapers as she may select."

"SCIENCE" states that the following Bill has been introduced into the United States House of Representatives and referred to the committee on coinage, weights, and measures:—"Be it enacted by the Senate and the House of Representatives of the United States of America in Congress assembled, that on and after the first day of January, nineteen hundred and five, all the Departments of the Government of the United States, in the transaction of all business requiring the use of weight and measurement, except in completing the survey of public lands, shall employ and use only the weights and measures of the metric system; and on and after the first day of January, nineteen hundred and six, the weights and measures of the metric system shall be the legal standard weights and measures of and in the United States."

THE FUNCTIONS OF TRICOLOUR FILTERS.

Paper read before the Optical Society, December 17th.

PART. I.

ALTHOUGH a great deal of theoretical work has been advanced upon the subject of the filter curves of tricolour filters employed for taking the negatives of tricolour photographs, there seems to be still a considerable difference of opinion on the subject. Examination of the filters at present on the market seems to point to the fact that too little attention is given to the point of the overlapping in the construction of such filters. The object of this paper is, therefore, to consider the effects of the overlapping and to show how this will affect the final colour reproduction.

We are not here dealing with the limits of photographic action, either at the red end of the spectrum (which is practically always limited by the sensitiveness of the plate), or at the violet end; neither are we dealing with the shape of the curves of photographic action, or the luminosity of the various spectrum colours. In passing, we should note that the curve of photographic action never corresponds with the visual effect, and the range of gradation which even the best dry plate will record is less than the eye can perceive.

One effect of this compression of the scale of gradation is to make the curve of photographic action steeper than the visual at the places where the filters absorb, and this, combined with the fact that the dyes generally used in making the filters have themselves abrupt absorptions, tends to prevent any gradual shading off at the limits of the filter records. This steepness is, moreover, enhanced in making the necessary chromated gelatine reliefs for transparency and paper work. We are not now attempting to put forward any final definition as to what tricolour filters should do, but merely suggesting a first step in their adjustment.

We consider that there is ample justification for our doing this, if only from the performance of filters now on the market. Some workers have thought that the curves of photographic action given by the tricolour filters should bear some direct relation to the curves of the colour sensations. They would, therefore, have excessive overlap, and we think we shall be able to show that any such filters will give too great a degradation of the reproduction colours. The only writer, as far as we know, who lays any stress on the amount of overlap, is Professor Miethe, who regulates its amount by a somewhat rule-of-thumb method.

In our tests upon the various filters we have examined we have preferred to use a fairly pure spectrum rather than trust to the, perhaps, doubtful effects of the impure colours of any colour sensitometer. The use of the spectrum was further necessitated by our wishing to measure the region of the overlapping. We consider that if any process of colour photography will give a fair reproduction of a spectrum, then it will reproduce any more complex colours well, since it reproduces their components, and we have taken this as the severest test we can apply. We believe this view is also held by Mr. F. E. Ives. Let us, here, carefully distinguish between the colour sensation curves, generally called "Maxwell's curves," and colour mixture curves. Maxwell's curves are not, as has sometimes been stated, curves obtained by matching each part of the spectrum by three pure monochromatic lights—these may be more properly called colour mixture curves (and were drawn by Maxwell)—but those usually known as "Maxwell's curves" give for every point of the spectrum the relative amounts of the three sensations which are stimulated in the eye, and which together make up the visual effect produced.

Some experimenters have taken the colour mixture curves, and others the colour sensation curves, as the basis of their

theoretical filters and inks. Whatever may eventually be found to be the best practical curves for the filters and their printing colours, we think we may state the two following fundamental points:—

First.—That since in any photographic process one prints from the parts of the negative where the light has not acted, or in proportion as the light has not acted, each printing colour should consist of white light, less the colours recorded through the filter.

Second.—That the regions where the photographic records overlap should accord in hue with the printing colours of the red and blue negatives. It is with this latter point we chiefly wish to deal in this paper.

It would be well, in passing, to examine a few of the definitions and tests that have been proposed by the various experimentalists in this subject. Sir W. Abney* states that the filters should follow the sensation curves and that the printing colours should be the exact complementaries of these, although in a paper before the Royal Photographic Society† he discusses the use of inks, and, hence, filters that have abrupt absorptions.

He proposes as a test for the filters, a colour sensitometer, in which the colours have been measured in terms of three monochromatic primaries; these are graded in sets so that each set contains a relatively equal amount of its own primary. A screen and plate are said to be adjusted when a photograph of its graded sensitometer gives uniform densities.

Now, we consider any colour sensitometer method such as this likely to give misleading results, because it would answer with filters passing only narrow bands, whereas, as Mr. Ives has pointed out, such filters would not render the colours whose regions of maximum luminosity happen to coincide with the colours not recorded. Moreover, the adjustment of filters by such a method would give no indication as to the form of their curves of action, and it would appear that the intention is for them to be adjusted to the sensation curves.

Mr. F. E. Ives, in the third Traill Taylor Memorial lecture, states:—"That the distribution of photographic action should correspond to Maxwell's colour mixture curves," and that the printing colours should be antichromatic to these.

Mr. E. Sanger Shepherd, in the Cantor lectures of 1900, after discussing the use of Maxwell's colour mixture curves, states that it is better for the filter records to follow Sir W. Abney's sensation curves, and proposes a sensitometer similar to that previously described as a test.

Mr. Howard Farmer states that it is best in practice to simply divide the spectrum into three bands, having no overlap, the junctions being at about the D line and a little beyond the F line in the blue.

Dr. Miethe, of Charlottenburg, has proposed the use of filters similar to those of Mr. Farmer, having no overlap, and dividing the spectrum at about 6,000 and 5,000, but states that these would give worthless results unless used in such a manner that an artificial overlap is produced by giving a second and shorter exposure with the next filter on the same plate. For instance, for the red record, he gives exposures through both red and green filters in the ratio of perhaps 15 to 1.

It will be seen from the above authorities that there is a great discordance of opinion as to what three-colour filters should do, and it will, therefore, be interesting to consider in detail how each spectrum colour may be reproduced by the tricolour process.

We may divide the spectrum as far as its photographic reproduction is concerned, into five regions, that is without taking into account any gradual shading off of the filter records at their limits. These regions are, firstly, those where only

* "Instruction in Photography." † "Journal of Photography."

red, green, or violet are recorded through their respective filters, and which are reproduced by the superposition of the printing colours in pairs. And, secondly, those which are recorded through the red and green, and through the green and violet filters, and which are reproduced by the printing colours of the violet and red records alone.

Let us suppose in Fig. 3* that our red filter and plate records from the beginning of the visible red I. (λ 6,900) up to III. (λ 5,820) at the end of the yellow, and, as from this negative we shall print upon the regions not recorded, let us print with a colour which consists of the summation of all the colours from III. (λ 5,820) to the violet end of the spectrum (λ 3,970). The hue of the colour obtained by combining all these wave lengths will be a greenish-blue.

Suppose, further, that our green record is from the beginning of the yellow II. (λ 6,070) to the end of the blue-green IV. (λ = 4,920), and that from this is printed on the parts not recorded, i.e., on the red region I. to II. and the violet region IV. to V., a colour consisting of the sum of the colours from I. to II. and from V. to VI., this will be a crimson.

Again, we will suppose the violet record extends from IV. (λ 5,020), the beginning of the blue-green, to the end of the violet VI. λ 3,970; the printing colour for this will consist of the remainder of the spectrum colours, viz., from the beginning of the red I. to IV., this is a yellow.

Let us now superpose the three prints and consider the nature of the reproduction colours. From I. to II. we have superposed the crimson and yellow, and we have to note what part of the incident white light will be transmitted. The yellow pigment will absorb the violet to which the crimson is transparent, and the crimson will absorb the green and yellow to which the yellow pigment is transparent; the common transparency will, therefore, be the region I. to II. Therefore, this region is reproduced by a uniform hue which is due to the sum of its own colours. This colour is a slightly impure red.

By reference to the sensation curves, Fig. 2*, it will be seen that not only the red, but a little of the green sensation is stimulated by the shorter of the included wave lengths, but, in spite of this, it is a sufficiently good red for the purpose, because it is as pure as any red one is likely to have to reproduce.

The second region II. to III. will have printed on it only the yellow pigment which transmits all the colours up to IV. λ = 5,020, and, on referring to the sensation curves, it will be observed that the spectrum yellow which stimulates only two sensations, the red and the green, is being reproduced by a colour, the components of which stimulate not merely the red and green, but also a little of the blue sensation, so that the spectrum yellow is reproduced with the addition, not of real white, but the sensation of white.

The yellow and greenish-blue pigments are superposed from III. to IV., and their common transparency corresponds to the same region, which is a green of slightly less purity than its central part. The greenish-blue, which reproduces the overlapping part IV. to V., stimulates the red sensation rather more than do the colours of the corresponding part of the pure spectrum. Finally, the region V. to VI., on which is superposed the crimson and greenish-blue pigments with a common transparency to the colours of the same region.

We might have, by integrating the areas of the curves cut off by the dividing lines in Fig. 2*, found the percentage composition of the reproduction colours in terms of the sensations, had we thought it worth the while. It will be noticed that we have drawn no distinction between the blue and violet of the spectrum; pure violet is a colour which one has practically never to copy. It is thus seen that in reproducing a spectrum

we do so with slightly degraded colours, and, as Dr. Clay has pointed out, this effect is least noticeable when the degradation is with white.

But we now wish to point out that this is immaterial, for when we come to consider the reproduction of the colours one meets with in nature and in pigments, this degradation with white in nearly all cases ceases to exist. Take, for instance, the reproduction of a yellow pigment. All yellow pigments transmit or reflect the red, yellow, and green of the spectrum, and some even a little violet, that is to say, they are already equivalent to a spectrum yellow diluted with white, and are, therefore, as impure as the colour with which they are imitated.

There are few greens to be met with whose spectra do not extend over a greater range than from λ 5,820 to λ 5,020, and so in their reproduction by the above system there is no addition to their impurity. One might cite many cases, but the whole point turns on the fact that although one may turn to the spectrum as a test, one does not in practice have to reproduce pure spectrum colours.

Considered from the point of view of the aforementioned treatment, the tricolour process by negative synthesis would appear to depend only indirectly upon the tricolour theory of vision, for the colours are approximately at least imitated independently of the mechanism of vision. It appears from the foregoing that the region which is recorded through both the green and the red filters is reproduced in the printing colour of the violet record, viz., a yellow; and that the region recorded through both the green and violet filters is reproduced by the printing colour of the red record, generally a blue.

Now, as one has, at present, to use reproduction colours which seldom give us what we require, we suggest that the amount which the red and green records fully overlap should be restricted to the region that corresponds most nearly in hue with the printing yellow to be used. Similarly, the completely overlapping region of the green and violet records should be confined to the part most nearly matching the blue or greenish-blue printing colour. We consider the overlapping should never exceed this, and, on the other hand, should never fall far short of it.

The gradual overlaps required by filters, based upon colour sensation curves, or intended to follow colour mixture curves, are seldom or never realised in practice. They are things which are talked about but seldom produced. Mr. Ives is the only person, as far as we know, who claims to have successfully used filters whose records correspond to colour mixture curves. We must give deference to Mr. Ives' statements, as he is a practical as well as theoretical worker. But some photochromoscope filters of his which we have examined only give a very crude approximation to colour mixture curves, and their excessive overlap is, we have found, fatal to their use for three-colour printing.

There is another point which seems to have been lost sight of altogether, and is, moreover, an objection which has not as much significance if the filters have fairly abrupt absorptions. In all molecular phenomena, i.e., in magnetism and electric response to stimulus to living or non-living bodies, in photographic action, etc., there is a period of ineffective stimulus, e.g., in the case of a photographic plate there is a certain minimum amount of light action below which no deposit of silver occurs.

Suppose now that by a certain exposure to a spectrum with suitable filter and plate, one obtained a silver deposit whose density corresponded to, say, the red colour mixture curve; if we gave any other exposure, then the shape of the curve ought to remain the same (except, perhaps, with great over exposure, when in any case all parts would tend to reach their maximum limit of density). But this would not be so, on

* The figures illustrating this paper will be reproduced in next week's JOURNAL.

reducing the exposure, the less dense parts would lose their density too rapidly and soon become clear glass while there was still a good deposit in the densest part. Fig. 4 shows what ought to occur on varying the exposure from the original, and Fig. 5* what does actually occur.

This shows that colour mixture and sensation curve filters will only work as they are intended to do when all parts of the subject to be copied have the same brightness. It is probably due to the maxima only having acted in some parts of the picture that the previous example shown was not worse than it is. Of course, this argument applies to all filters only in greatly varying degree, but filters having marked maxima will act differently in copying light or dark colours.

In view of the rapid growth of the application of tricolour, especially to photomechanical processes, it is a matter of commercial importance as well as of theoretical interest to know what one wants, even very approximately, in the construction of the filters and the selection of inks. So confusing is the present state of affairs that few tricolour operators in the process trade have any idea of what they require, and they are guided by rule of thumb considerations only.

PART II.

We have examined several sets of commercial and recommended filters, by reproducing a fairly pure spectrum with them. The regions of the spectrum recorded through them, and also the approximate distribution of the colours in the reproductions, are given in the two tables accompanying this paper.

The reproductions of the spectrum we are about to show were made with superposed gelatine reliefs, dyed with erythrosine, brilliant yellow, and fast green (blue shade). The peculiarities of the reproductions made by means of the various filters are as follows:—

* See note on page 48.

TABLE I.—SHOWING THE REGIONS OF THE SPECTRUM RECORDED THROUGH CERTAIN TRI-COLOUR FILTERS.

FILTERS.	RED RECORD.	GREEN RECORD.	VIOLET RECORD.
Ives (Kromskop) ...	6,520 to 5,250 (maximum effect 6,480 to 5,800)	6,300 to 4,700 (maximum effect 5,700 to 5,250)	5,050 to 3,800 (maximum effect 4,950 to 4,500)
Farmer and Simmons ...	6,500 to 5,700 ...	5,850 to 4,550 (with a minimum 5,300 to 4,900)	No. 1, 4,500 into ultra-violet; No. 2, 4,850 to 4,350
Sanger Shepherd ...	6,340 to 5,710 ...	5,900 to 4,950 ...	4,820 to 3,800
Lumière ...	6,640 to 5,860 ...	5,420 to 4,800 ...	4,730 into ultra-violet
Lumière N.A. Co. ...	6,580 to 5,760 ...	5,800 to 4,660 (maximum effect 5,800 to 4,900), also slight effect in ultra-violet 3,890 and beyond.	4,700 into ultra-violet
Klein (for collodion emulsion)	6,470 to 5,470 ...	5,900 to 4,950 ...	Chief effect—5,100 to 4,500, tailing off to 3,800; Slight effect—6,000 to 5,830

TABLE II.—SHOWING APPROXIMATELY THE REGIONS OF THE SPECTRUM WHICH ARE REPRODUCED IN THE COLOURS INDICATED.

Filters.	Unrecorded Red (reproduced as Black).	Red.	Yellow.	Green.	Blue or Greenish-Blue.	Blue-Violet.	Black.	White.
Ives ...	6,900 to 6,520	6,520 to 5,800	5,800 to 5,300	5,300 to 5,000	5,000 to 4,750	4,750 to 3,800
Farmer & } No. 1 ...	6,900 to 6,500	6,500 to 5,850	5,850 to 5,700	5,700 to 4,500	4,500 to 4,550	4,550 & beyond
Simmons } No. 2 ...	6,900 to 6,500	6,500 to 5,850	5,850 to 5,700	5,700 to 4,850	4,850 to 4,550	4,550 to 4,350	4,350 to 4,000	...
Sanger Shepherd ...	6,900 to 6,340	6,340 to 5,900	5,900 to 5,710	5,710 to 4,950	...	4,820 to 3,800	4,950 to 4,820	...
Lumière ...	6,900 to 6,640	6,640 to 5,860	...	5,420 to 4,800	...	4,730 & beyond	5,860 to 5,420	...
Lumière N.A. Co. ...	6,900 to 6,580	6,580 to 5,800	5,800 to 5,760	5,760 to 4,700	3,890 to 3,550	4,700 to 3,890	4,800 to 4,730	...
Klein ...	6,900 to 6,470	6,470 to 6,000	5,830 to 5,470	5,470 to 5,100	5,100 to 4,950	4,950 to 3,800	4,900 to 4,780	5,000 to 5,830

NOTE.—For comparison with the figures in this table, it may be interesting to note the positions of the various colours in the spectrum. From the beginning of the visible, about λ 6,900, to λ 6,200, is a pure red. From this point an orange tint is gradually assumed until it becomes a distinct yellow at λ 5,900 to λ 5,780. The green region lies between this and λ 4,900, there being a gradual change from a yellow-green to a blue-green. From λ 4,900 to λ 4,600 is a deep blue, and from λ 4,600 to the limit of visibility, about λ 4,000, a violet.

Red filter contains potassium bichromate, eosin, and ammonia, and it is used with a Lumière B plate.

With these filters the part that is reproduced yellow is in the yellow-green; there is the degradation of the blue-green noted above, and with the second blue filter the extreme end of the violet is reproduced as black; but as its luminosity is low, it probably is not of much consequence.

Sanger Shepherd's Filters for the Spectrum Plate.—The photographic records with these filters end somewhat abruptly. The red is not recorded quite as far as with the other filters; this is due to the peculiarities of the plate used. The band reproduced as yellow is too broad, extending from the truer yellow into the green at λ 5,710, while in the blue there is a narrow band of black.

Filters from Messrs. Lumière, of Lyons.—the red, green, and blue filters are used with the Lumière B, A, and extra rapid plates respectively. They give three isolated bands of red, green, and blue-violet only, of fairly correct hue for the positions they occupy, but the intermediate parts are reproduced as black, as they are not recorded at all. The ultra-violet is reproduced as blue-violet.

Filters from the Lumière N.A. Co.—Used with the same plates as the last. The reproduction with these is fairly good, except that all the colours are shifted a little towards the blue end. The narrow band of yellow is in the yellow-green, and the green extends into the blue. The slight transparency of the green filter to ultra-violet causes a region there to be reproduced blue.

Klein's Filters for Collodion Emulsion.—These are used with Albert's collodion emulsion. For the red filter the emulsion is sensitised with Penrose's "C" sensitiser, and for the green filters with Albert's "A" sensitiser. The most peculiar point about these filters is that the blue one consists of a dye that absorbs green only, and as the sensibility of the "A" sensitised emulsion extends into the yellow, this colour is slightly recorded through the blue filter, and being also recorded through the other two is reproduced as white. The part that is reproduced as yellow is the less refrangible half of the green. The remainder of the spectrum is more correct.

It occurred to the authors that it ought not to be difficult to make a set of filters that on a good panchromatic plate would give a reproduction as good or better than any of these. We, therefore, dyed up a set of dry filters with methylene blue, naphthol green and scarlet, and these, when roughly adjusted, gave on a plate dyed with Miethe's ethyl red the following spectrum records:—

Red filter	6,500 to 5,850
Green filter	5,900 to 4,650
Blue filter	5,000 to 3,600

We found that these gave a fairly good, but not by any means perfect, reproduction of the spectrum. The overlapping portions being here restricted approximately to the hues of the yellow and blue printing colours, and there being no stray portions of light coming in where they are not wanted.

The last set of records that we have to show emphasise two points already mentioned. The filters are methylene blue, naphthol green, and scarlet R.R., used on a Lumière C plate. The red filter was adjusted visually and well illustrates the facility of such a method, for, as will be seen, its photographic record shows that it is transparent to light beyond the visible violet. The green filter has been under-exposed, and shows as a consequence the degradation of the green with red due to a band of insensibility in the plate and a black band in the yellow.

The degradation of greens is a matter of great importance in tricolour work. It is of constant occurrence, and there are several causes tending in the same direction.

1. Excessive overlap between the red and green filters, whereby an insufficient amount of blue occurs in the print.

2. The comparative insensibility of most orthochromatic plates to blue-green, which results in an excess of red being printed on them. This is really a case of the filter record having maxima, a point we have discussed.

3. The want of transparency to green, of most of the blue printing colours, and their slight transparency to red.

To summarise our suggestions:—

1. Printing colours should be transparent to the colours not recorded by their respective filters, and are not to be merely complementaries (except that the blue printing colour must not transmit the extreme red which is never recorded).

2. Complete overlapping regions to accord in hue with yellow and blue printing colours.

3. Records to be without maxima (or minima) over the regions where complete record is required.

A. J. BULL and A. C. JOLLEY.

PHOTOGRAPHIC MUSEUMS.

OUR age is remarkable for the great zeal shown in collecting anything—the products of nature, art, and industry into museums, all that the human mind has thought and invented into libraries and archives. Only photography had been forgotten, for it is too young an art; but it does the greatest service to science, art, and industry. Its productions have been very often exposed in a great many exhibitions, but the photographs shown there for a short time are afterwards dispersed over all the world, and nobody has thought of preserving the artistic and other interesting photographs for posterity.

An Englishman, Mr. W. Jerome Harrison, was the first who meant that a great many works of Daguerre's art merited a better fate than to perish unknown, and were worthy of being preserved for the profit of the men of our own age and future generations. Mr. Harrison read, therefore, at the Photographic Congress of Chicago, 1893, a paper, in which he exposed the necessity for all nations to create international collections, with the possibility and intention of exchanging photographs with each other. The paper was heard with great enthusiasm by the members of the Congress, who chose an international commission for the study of the question, but nobody heard anything of it afterwards, which is usually the case with resolutions at international congresses.

Happily for this important matter, a member of the international commission, a Professor of Arts, Léon Vidal, known as an authority in the photographic world of Paris, had understood the great value of such an international collection, not only for professional photographers and amateurs, but also for every science and art, for history, and public life. Mr. Vidal possessed also all the qualities necessary for the execution of such a task with success; in one word, he was the right man in the right place.

Mr. Léon Vidal was right in thinking that such a problem could not be solved only by meetings of isolated friends of photography, but by corporations, who could alone possess the authority required. He addressed himself, therefore, in 1894, to more than thirty scientific, technical, artistic, and photographic societies, who conceived entirely the great use of this collection for the cause they represented, and they founded the Association du Musée des Photographies Documentaires, to which the booksellers gave asylum in their club-house (Boulevard St. Germain), and nominated Mr. Léon Vidal as president. This enterprise had an unexpected success. Editors, amateurs, and professionals, men of science and art, gave variable gifts, and now, after ten years, the museum

possesses 80,000 photographic documents (December, 1903). It is international, and accepts gifts from all friends of photography in other countries, which are examined by a commission, and if found worthy are incorporated in the collection and mentioned in the catalogue. The institution is very well organised, and every new addition is catalogued immediately after reception. The principle followed by the compilation of the catalogue is the same as that of public libraries, with some modifications for such matters as philosophy, philology, etc., which are represented by a great many books in libraries, but offer little interest for photographers.

Such collections can do the greatest services to photography in preserving its best and most interesting products for posterity, and also to science, art, and history, by keeping these important documents, which may be useful for scientific studies in the future. An example of the importance of photography for the history of our time is the instantaneous photographs of an amateur, made at the Buffalo Exhibition, where the scene of the assassination of President MacKinley is depicted exactly.

The Musée des Photographies Documentaires is also an indispensable addition to all public libraries and archives, for these institutions possess no iconographical catalogue, and it is impossible to find there any particular illustration contained in a volume without a special catalogue, whereas, in the photography archives it will be found immediately. Such an institution is also of the greatest use to editors, printers, and publishers of illustrated journals, who will find there precious materials for their publications.

The greatest difficulty in preserving the products of photography consists in the bad quality of the paper which is used, and which is destroyed after a few years by the humidity of the atmosphere. But the museum of Mr. Léon Vidal employs paraffin, by a special process, to enable them to resist for a long time all exterior influences. The rooms of the Paris Museum des Photographies Documentaires are now, through the unexpected increase of the collections, insufficient, and the direction has therefore asked the President of the Municipal Council of Paris to give to this Institute some rooms in the Petit Palais in the Champs Elysées; the negotiation will soon be closed, and when the museum has sufficient rooms, it will be one of the greatest service to science, art, and photography. In England, whence the idea issued by the paper of Mr. Harrison, Sir Benjamin Stone founded in the year 1897 the National Photographic Record Association, which has collected views of ancient houses and historical monuments of London, such as the Tower, Westminster Abbey, the Houses of Parliament, and which deposited, in the year 1900, its collection in the British Museum for the use of the public. This association is not international, as that of Paris, but only destined for photography concerning the British Isles. It possesses now more than 3,000 documents, and will be of great use to students and historians. The association is connected with a great many other photographic societies in England, as Chorley, Croydon, Darwin, Hertfordshire, Leicestershire, Liverpool, Nottingham, Paisley, Redhill, Rutland, Somerset, and has written a paper to these societies suggesting the method to be followed in photographing all the remarkable monuments of the respective districts.

In Belgium, a Musée Belge des Photographies Documentaires has been founded in 1901, with the aid of the Photo. Club Belge, under the presidency of Mr. Ernest de Potter, very well known in photographic society at Brussels, on the same principle as the museum of Mr. Léon Vidal.

In Switzerland, at Geneva, has been founded the Musée Suisse des Photographies Documentaires, in the same year, under the presidency of Dr. Demôle, which has also adopted

the same organisation as the institute of Paris, and has, with a very little expense, collected now about 15,000 interesting photographic documents. The museum, for the first three years a private enterprise, is to be the property of the town of Geneva, where a new Museum of Arts is being built, which will be opened this year, and where some rooms are destined for the photographic museum. The Canton of Vaud possesses also a photographic museum at Lausanne, with Mr. Paul Vionnet as conservator. Germany and Austria, although photography has taken there a very brilliant development, have been a long time indifferent to this movement, but now their interest has been awakened by the photographic press. Different photographic reviews have described the museums of London, Paris, Geneva, and Brussels, and a committee has been founded for the purpose of the creation of similar institutions in Germany and Austria.

The most important countries of Europe are thus persuaded of the necessity of the photographic museums, or archives, and the other countries will soon follow this example. The first part of Mr. Jerome Harrison's proposal at the Photographic Congress at Chicago in 1893, "the creation of international collections," now, after twelve years, will be realised; but the second and most important part remains yet to be realised, that is, "the international exchange of these collections."

Mr. Léon Vidal thinks that this other task of the different photographic museums is only to be solved, if all these archives now founded, or to be founded, are organised on the same principle, for the question of the photographic museums is an international one.

ERNEST MORGERNSTERN.

ASTRONOMY IN THE HIGH SCHOOL.

[From "Popular Astronomy."]

The late article on "The Small Telescope in the High School" by the senior editor of "Popular Astronomy" are very suggestive. They have led me to formulate the following short confession of astronomical faith as regards practical teaching in elementary astronomy.

In my judgment we who are teachers of beginners should hold fast to two ideals. We should lead and inspire our students to be watchers of the heavens, friends and lovers of the stars. We should maintain symmetry and proportion in dealing with the wealth of material offered by the oldest of the sciences.

As a guide in realising these ideals, we may well take the work of astronomers in the large, making, however, no attempt to use their fine tools or obtain their high degree of accuracy.

Now, astronomers study the heavens with two widely different objects in view. The "bright orbs" overhead, like powerful genii of the lamp, are invoked to further simple human undertakings. The stars help us to find latitude, longitude, and time. On the other hand, the whole heavenly array, sun, moon, stars, nebulae, planets, comets, and meteors, are watched and studied not that they may help us, but that we may find out about them.

A glance at the different investigations connected with these two main objects will show that the fundamental problems of the astronomer have usually their humble counterpart within reach of our students. They cannot regulate standard clocks to a small fraction of a second, nor make definitive determinations of latitude. But they can compare their watches with a sun-dial and from the shadow of a gnomon find how many degrees it stands north of the equator. They are able to take no part in the cataloguing and charting which fix star-places for use at observatories. But they can become familiar with the constellations and call the bright stars by name. To unravel the tangled web of real and apparent motion, to predict not only the position of bodies in their orbits but the form and position of the shifting orbits themselves—these things are beyond the reach of beginners. But they can measure the sun's altitude at noon and its azimuth at

setting, and track the course of the planets as they wind in and out among the constellations. While it is a thing too hard for them even to grasp the meaning of the methods employed in astro-physical study at the Lick and Yerkes Observatories, they may watch spots on the sun, identify lunar markings, and note Algol's shifting light.

I should therefore conclude that for substance of doctrine the following list of subjects should stand as fundamental in any scheme for the practical study of elementary astronomy.

1. The Constellations.
2. Diurnal Paths of Sun, Moon, and Stars.
3. Paths of Moon and Planets among the Stars.
4. Latitude and Time.
5. Use of Opera-Glass or Small Telescope.

There is a mistaken notion that such a scheme as this is simple and easy. I thought so once myself. Enthusiasm and love of one's work are powerful enchanters. And yet, as I look back calmly and coolly on my painstaking efforts for more than a score of years to work this course out with real boys and girls in High School, Academy, and College, I am ready to recant. The work involved is about the hardest that a teacher can undertake. None but those who have held star-watches on many nights of many years know how difficult it is to co-ordinate time, phenomena, and pupil. No cunning mathematical formula in the theory of probabilities will enable us to predict for any given evening the actual configuration between stars, students, and clouds. We are practically denied both workshop and tools. In this present dark age of elementary astronomical teaching, High School instructors might about as well demand to have the stars themselves brought down to the schoolroom as to ask for an astronomical laboratory. They usually obtain only by toil of soul and sorrow of heart so much as a north and south line and a place to see the sky. Ah, if so many trees did not grow in the wrong places, if only a meridian line could be bought and set up (or rather down) as telescopes are!

It falls to our lot, also, to contend with foes within as well as without. Our very liberties bring temptation, since as yet there is no core of instruction recognised everywhere as essential, it is, on the one hand, only too easy to neglect continuity and detail and lead our students into by-paths here and there, where things curious rather than fundamental take their time and attention. Especially is this so, if we have worked out a neat method of reduction or devised some little instrument that is to be brought into use. On the other hand, we are beset by the temptation to turn away from the little, simple things, and by a process of forcing, carry our students through what we are pleased to call real astronomical work. The thing sounds well, looks well perhaps in print; but can be attained only by ignoring proportion in our teaching, neglecting the foundations of astronomical knowledge, and leaving students in the end fitted to do well neither elementary nor advanced work.

It is seldom the part of wisdom to shut our eyes to real dangers in the path before us. But from my own point of view, the conclusion of the whole matter is this. It were better to fail in teaching elementary astronomy according to practical methods rather than win apparent success in the old ways, long since discarded in other sciences.

MARY E. BYRD.

Smith College Observatory, Northampton, Mass.

THE Board of Education, in co-operation with the Council of the Society of Arts, intend during the present year to hold, in the Victoria and Albert Museum, South Kensington, an exhibition of Engravings produced by mechanical means, such as photogravure and other photographic processes, as a sequel to the exhibition of engraving and etching held during last summer; and, as great advancements have been made in printing in colours since the Exhibition of Modern Illustration in 1901, specimens of colour-printing will be included. A committee, of which Sir William Abney, F.R.S., will act as chairman, has been formed to advise the Board in carrying out the exhibition. All communications should be addressed to the secretary, Exhibition of Mechanical Engraving, Board of Education, South Kensington.

FIFTY YEARS AGO.

[From the "Liverpool Photographic Journal" (now the "British Journal of Photography"), January 14th, 1854.]

THE Liverpool Photographic Society, in putting forth a Journal of their own, rest their claims to public support upon the widely extending interest in the several branches of photographic art—the progress that is being made by the practical members of their society and other photographers elsewhere. The admirers of the art naturally desire to have more particulars, and the practical operators more full and precise records of the suggestions, experiments, successes in various parts of the world, than can possibly be afforded by a newspaper devoted to general information. The "Liverpool Photographic Journal," though furnished with the proceedings of the Liverpool Society from the commencement, has not been able to find room for them, a part only of the May meeting being given in the September number. The Glasgow photographers obtain their information of our proceedings through the medium of American newspapers!

An Exhibition of Photographs has been proposed to take place during the visit of the British Association to Liverpool. In conjunction with this, the Liverpool Photographic Society have offered premiums for the best specimens of the art produced by their members. A premium has also been offered by the British Association for the best photograph of the moon—for which it is expected resident photographers will compete. The award of the premium offered by our society will be influenced, if not decided, by the opinions of the British Association; but it is desirable that public taste should be brought to bear upon it, and to cultivate the appreciation of the beauties of the photographic art—the quality most valuable, most to be admired—the society propose this publication, in which not only all the papers read at the meeting will be published, but the discussions upon them, in the course of which individual observations and suggestions occur of the highest importance, though they may not be appreciated at the moment in consequence of some other matter being the absorbing point of interest.

The Liverpool Society have therefore deemed it expedient to publish a Journal of their own, commencing with the report of the meeting in the new year. But, that the records preserved may be complete, a résumé will be given of what has already been done by the society, with such papers as may be considered interesting to those which have been read at previous meetings. The proceedings of the London Society and of independent operators at home and abroad will be given, with everything that can be obtained to furnish our readers with a complete account of the state and progress of the art in all its various branches.

Various forms of camera adapted to photographic operations have been exhibited by Mr. Mackinlay, Mr. Wood, Mr. Atkinson, and others, members of the society, of which full descriptions will be given. A set of rooms have been engaged for reading and operations, and furnished with many of the works—Continental and English—esteemed the best authorities on the several branches of photography, and a camera of the best description, with screens, baths, and every requisite for the practice of the art.

Valuable contributions have been made to this society. Three Dr. Edwards, Mr. Sanford has presented a number of very fine photographs. Mr. G. R. Berry has presented some specimens of lithography and photographic engravings on steel. Mr. Mackinlay, Mr. Forrest, and Mr. McInnes have been devoting their attention very successfully to making the means of the collodion process portable; and the latter gentleman has developed a method of moving the collodion film from the glass without injury to the photograph—in some instances even improving the appearance. Mr. G. R. Berry has perfected a paper process, in which he can print a beautiful colour by gaslight, of which the members of the society will have a full opportunity of judging, through the liberality of another member, Mr. John Morecroft, who has sent a number of negatives taken with wonderful success and judgment by Buckle's process, of which impressions are to be printed by Mr. G. R. Berry for the purpose of distribution to the society—two prints to each member. Mr. G. R. Berry gratuitously contributes his labour in printing these exquisite photographs for the society, in which all members will receive the full value of their subscription.

Mr. Bell has produced some very minute daguerreotypes for

ereoscope. Mr. Frank Howard has been endeavouring to persuade us to confine our attention to facts, without attempting to compete with the Fine Arts; and has also assisted to put us in possession of those principles of chiar-oscuro which have been, and are, recognised as essential in works of the Fine Arts, in case we should reject his advice as to the limitation of efforts to truth and scientific illustration.

Dr. Edwards has exemplified the use of photography in preserving life-size representations of rare specimens of natural history by collodion photographs of the "torpedo nobiliana" recently caught off these shores; and by various microscopic details, preserved on collodion, with the assistance of Mr. Barker, and exhibited with unquestionable accuracy.

Another instance of its utility has been shown in the interesting series of photographic reports of the progress of the Crystal Palace, erected at Sydenham, which Mr. Archer, the Liverpool agent of the Crystal Palace Company, has displayed before the society on two occasions. Every week Mr. Delamotte takes a photograph of various parts of the works, which are then printed and sent to the directors of the company, as reports of the progress, in which no mistake, falsification, or cooking can occur or be practised.

The architects are aware of the value of photography for these and similar purposes, and the Liverpool Architectural and Archaeological Society has invited a member of our society to read a paper on the practice of the art as applicable to their wants.

The authorities of the British Museum are applying photography to preserving and distributing records of the treasures in their charge. The curator of the Derby Museum may do the same.

It has also been suggested by one of our members that photography could be applied in assistance of physiognomy and ethnology, by preserving records of the natives of the various countries with which we have commercial intercourse, and who are daily visiting this port in such numbers and variety as to afford the most favourable opportunities for such contributions to science.

The success of the Kearton Exhibition of Nature photographs at the Modern Gallery, Bond Street, has been so great that Messrs. Kearton have decided to continue the exhibition of their pictures until February 13th.

A CATALOGUE of several hundred pages reaches us from the well-known Indian firm of dealers in photographic apparatus and materials, Messrs. Babajee Sakharan and Co., Esuf Buildings, Bombay. It is all compiled and contains a great deal of useful practical information.

THE year 1905 being the tenth anniversary of Röntgen's discovery of the X-rays, it is proposed to commemorate the occasion by holding in Berlin a Röntgen congress, together with a Röntgen exhibition. Information regarding the arrangements will be obtainable from Prof. Eberlein or Dr. Immelmann, of Berlin.

At the Westminster Police Court, on January 12th, William Morrison Pouch, 47, artist and photographer, of Ebury Street, Pimlico, was, on warrant, charged before Mr. Horace Smith with obtaining £21 by false pretences from Edward Fuller Cripps. Prisoner, recently of Exhill, has, it was alleged, extensively advertised for pupils to learn all branches of photography. It is alleged that he has obtained large sums of money for premiums though he had done practically no photographic business. The sworn information of Detective Chatt was that he had carried on the system at various places in the provinces for the last seven years, and Detective-Sergeant Smith stated that after arrest he detailed to prisoner a list of persons from whom he had obtained sums of from £100 to £25, the aggregate amount approximating £1,000. The defendant, in reply, said he did not see how they could make out any false pretences, as in return for the money he gave time to pupils and taught them. The witness took exception to his statement, pointing out that some of the complainants were not pupils but entered his employment believing his assertions about the business. The witness added that the prisoner was entirely without means. He had only a few coppers when apprehended. The servants of the studio had had no money for months, and several young men had lost the whole of their capital. Owing to the large amounts involved, the police asked for legal aid. Mr. Horace Smith said he could certify for that, and remanded the prisoner in custody.

OVER-PRODUCTIVENESS IN PHOTOGRAPHY.

"Do you suppose," said an artist of repute the other day, chatting with a photographic friend over coffee and cigars at a hotel not far from Burlington House, "that if an oil painting were as easy to produce as a photograph, and the supply of one were as plentiful as the other, the former would long maintain its supremacy among connoisseurs? No, leaving aside the question of colour, and the painter's larger degree of control, it is certain that many of the pictorial photographs we see at present would instantly win equality with the average painting if it were not for the stigma placed upon them by their facility of execution and the over-productiveness of photographers."

The foregoing liberal-minded pronouncement is interesting and suggestive. It is probably true that the almost universal use of the camera, and the consequently large amount of mediocre work scattered broadcast everywhere, is detrimental, in a sense, to the artistic status of photography. The sun picture has been made too common. We seldom hear anyone speak of the least pretentious pencil sketch with that semi-patronising and indulgent tone often used in discussing the camera. Worst of all, should the latter happen to be a pictorial triumph, the ordinary inexpert critic will most likely express his satisfaction that it is "so unlike a photograph!" a verdict apt to make its unfortunate recipient grind his teeth in impotent rage.

A well-known New Gallery exhibitor was recently heard to venture the opinion that there was no possibility of pictorial photography ever ranking in general esteem with the recognised fine arts, until some kind genius should invent a fresh process, better than any now in use, and having the saving virtue of exceeding difficulty. "When we have an art," quoth he, "which only a few will be able to acquire successfully, a future of undreamed greatness will lie before us."

Somewhat the same idea, but viewed in a more commercial light, was evidently in the mind of a certain professional of the old school, who was regretfully comparing the palmy days of Daguerreotype and wet collodion with these evil times of cutting prices and small profits. In his view, it was all because the gelatine process was so criminally easy. If the studio owners of the bygone period had known what the introduction of the dry plate would mean to them, the inventor's existence, he averred, would have come to a speedy and painless end.

It is never any use crying over spilt milk, however. As Tennyson says somewhere, we must

"Set ourselves to face the hour,
But dream not that the hour will last."

The days of no competition are probably as unlikely to reappear as the oft-quoted Mastodon; the only line open for the improvement of photographic prospects lies, apparently, in an attempt to educate the public taste to a better appreciation of the artistic aspect of camera work. Now, undeniably, as has been suggested, one way of doing this would seem to be to limit the supply of pictorial photographs, to make them at least less prodigally abundant.

We see photographers divided into two sections, broadly speaking: those who are content with what is simply a photograph, mechanically produced for matter-of-fact purposes, and the much smaller number who are satisfied with nothing less than what they regard as a picture. It is only natural that the former, looking at things in a frankly business aspect, should favour a large production and a multiplication of copies, but surely we might expect a different ideal from their more thoughtful and art-loving brethren.

Why cannot the pictorial photographer, by a wise self-repression, materially check his output, resolving firmly, for instance, that there shall be no further copies of a successful work, except in the way of reproductions? He is perpetually in high argument with the artist, who rejects the claims of photography to rank as an art, capable of expressing creative intention, yet he immediately proceeds to do the very thing which, perhaps, before all others, has led to such an attitude of hostility. We do not hear of the artist painting a dozen copies of a favourite picture, or of the sculptor allowing as many replicas of his best achievements. The artist of the camera would be well advised to take the hint. Indeed, if it were not a hard saying, savouring of flagrant heresy, we would urge the pictorial worker, his medal picture once achieved and its permanency undoubted, to hesitate not a moment, but—oh daring and awful suggestion—to smash the negative. Any after prints would then have to be made from a copy.

failing, deliberately, to be quite as good as the original, which would thus preserve an undivided and unique prestige.

Still speaking from the pictorial standpoint, and without the least wish to dogmatise, is it not possible that we do too many pictures? The truly artistic temperament prefers a lesser quantity and a higher quality. Why need we feel ashamed or dissatisfied if we have but one frame to show for a six months' work, if only that one is a masterpiece in its way, worth twenty others put together? Cannot we learn to have a better ambition than the mere filling up of wall space? Could we not school ourselves to know and believe that one tiny print may be more worthy of notice and enthusiastic praise than the whole remainder of entries in an exhibition?

We have said "one tiny print" just for the sake of emphasis; but is it not a fact that there is a decided tendency among us to worship mere size? We will often exhibit an imposing enlargement from a negative which would hardly meet with our approval in its original dimensions, as if there were a special virtue in added inches. And how condescendingly the small print is sometimes spoken of, as if some guilty flaw lurked within, needing apology and condonation. Yet several of the finest paintings extant are extremely diminutive. There is a certain splendid allegorical conception of Raphael's in the National Gallery which is almost priceless, while Meissonier's exquisite little gems are admittedly his best.

It is not intended to suggest for a moment that the photographer should do less work, or spoil a lesser quantity of plates and paper. That would not be the way to gain and keep a perfect mastery of his tools. Rather would we urge him where he now exposes one plate to expose fifty, where he prints one proof to reject a dozen, before he allows himself to be satisfied. But we would strenuously impress on his inmost consciousness the need of showing, exhibiting, and distributing less. So shall his pictures take a greater and more honourable place in the world of Art, and in that popular favour which, fickle and arbitrary though it be, accurately reflects, on the whole, a sober and truthful judgment in matters of taste and culture.

A. LOCKETT.

New Apparatus, &c.

The Mawson Plates. Manufactured and sold by Messrs. Mawson and Swan, Mosley Street, Newcastle-on-Tyne.

We have received from Messrs. Mawson and Swan samples of three new series of plates for trial and a specimen colour filter for use with their A and B series of orthochromatic plates. To those familiar with the various brands of dry plates there can be no doubt that great progress has been made by manufacturers within the past two years in point of speed of emulsions. The extra rapid plate of former years has been surpassed, and we find that Messrs. Mawson and Swan have not been slow in meeting the wants of the photographer by producing a plate of exceptional sensitiveness. The "Celeritus" Plate: This new series is of extreme rapidity, and in these dull winter days we found they gave good results even with very brief exposures. The quality of the emulsion is excellent, being fine in grain, clean, and capable of withstanding a developer with a large proportion of alkali. For studio work in dull winter weather, and for sitters of the restless and nervous types, this series will be found most useful. For difficult hand-camera work it should also be of great value. The "Felixi" Plate: This series is issued at popular prices, but although cheap it will bear comparison with some of the highly sensitive plates now on the market. The emulsion is surprisingly good, and though very rapid, of peculiarly fine grain and quite free from any trace of fog. We tested its resistance by reducing the exposure and forcing the development, and found that the shadows remained clear, notwithstanding the addition of an abnormal quantity of accelerator to the developing solution. As the plates are liberally coated and withstand such harsh treatment, we believe they will be much appreciated by Messrs. Mawson and Swan's clientèle, both professional and amateur. The "Ortho B" Plate: This orthochromatic series has remarkable characteristics. As in another orthochromatic plate of English manufacture which we have recently used, we also find in this such truth of monochromatic rendering of colour, extending even to the red, that we infer the use of an improved

colour sensitiser. Although Messrs. Mawson and Swan remark their circular that the plate is sensitive to the whole of the visible spectrum, excepting a strip in the red between the lines A and D, we look upon this exception as one made in the interests of scientific accuracy rather than as a warning of practical importance. In our trials with the colour filter issued by them for use with these plates we found good rendering of three selected shades of red, ranging from the orange type to crimson, whilst pale blue was represented by a deeper tone than bright yellow. As the plate combines high speed with colour sensitiveness, it is deserving of special attention. It thus brought within the range of ordinary work, notwithstanding the use of the screen. In conclusion, we feel we ought to express our satisfaction with the quality of the screen, which is a necessary adjunct to the plate if correct translation of colour is desired. It is not only well adjusted to the colour sensitiveness of the emulsion, but it is highly commendable for the quality of the glass surfaces. Photographers are too apt to disregard this important point. Money is spent on the purchase of expensive lenses of excellent defining power, but the advantage is frequently nullified by the bad quality of the glass of which the colour screen is made. The price charged by Messrs. Mawson and Swan for these screens is very moderate, but if we except the specially worked article, as sent out by our best opticians, the screen we have before us is one of the best we have examined for flatness of surface.

The Farrington Picture Postcard Frames Sold by W. Butcher and Sons, Camera House, Farrington Avenue.

Messrs. Butcher are introducing a series of cardboard frames for holding picture postcards. Detachable struts may be inserted in the backs of the frames in two directions, so that the card may be viewed either in an oblong or vertical shape. Nine sets of designs are issued.

the opening measuring $4\frac{1}{2}$ by $3\frac{1}{4}$. The specimen set submitted to us is in excellent taste, and the idea being so good and apposite we have no doubt picture-postcard collectors will appreciate these neat little decorative adjuncts. The illustration gives an impression of the totality of effect obtainable.

The editors of "Camera Notes," published at 9, Nelson Villa, Bath, ask us to state that a free copy of that publication will be sent to any professional or amateur photographer on application.

New Books.

"Winter Pictured," by Rudolf Eickemeyer, jun. Price, 2 dollars. New York: Published by R. H. Russell.

If we remember aright Mr. Eickemeyer first attracted attention in English photographic circles by the exhibition of a print from a negative of a wintry landscape, in which snow and shadow constituted the principal themes. His very successful technical treatment of the subject led to considerable imitation, so that for a time you rarely saw a public photographic exhibition on the walls of which the Eickemeyer influence and sentiment were not evidenced. The large and handsome volume before us is a reminder that whilst Mr. Eickemeyer's imitators have either ceased to imitate him or have disappeared from the exhibition world altogether, he himself has steadfastly clung to the early ideal, of which it is plain he wishes us to consider the book, in one sort, the manifested realisation. These fifty or more winter landscapes, with suitable quotations from the poets printed underneath them, offer a valuable lesson to the photographer who would use his camera, lens, and plate with definiteness and consecutiveness of purpose. Mr. Eickemeyer set himself the task of illustrating by photographic means a series of aspects or phases of nature, and the result is a very beautiful collection of views full of subtlety, delicacy, and withal truth of rendering. We used the word "sentiment." It is obvious to us that Mr. Eickemeyer is in such sympathy with his subject—so keenly feels, as it were, the effects he sets himself to photograph—that he has no difficulty in conveying a like impression to the students of these photographs. They are so splendidly natural and "real looking," the children say, that one may be pardoned for shivering as one turns over the leaves. The accompanying text is judiciously chosen; the book is thoroughly well printed and turned out, and it should find its way into the possession of every lover of good photography.

Photographer's Catalogue. Published by Messrs. Langflier, Ltd., 23a, Old Bond Street, W

This Catalogue is perhaps not the best way of describing the elegant and artistic production before us; and it cannot properly be termed a price-list, for actually it is neither the one nor the other, although its mission is obviously of the two-fold character hinted at. Messrs. Langflier call themselves "artists in portraiture," and the volume contains numerous reproductions in colour and monochrome of the charming portrait work which has brought them fame and success. The blocks are superb in quality, the printing faultless, and we have nothing but high praise for the entire turn-out of the book. We wish all photographers possessed the taste and enterprise of Messrs. Langflier. The following extracts from the book should prove of general interest:—

"Amateur Theatricals.

"In order to meet the demands of amateur theatricals, we have made provision on a very high scale, and one of the features of our establishment is a stage with a regular proscenium, constructed especially for the use of ladies and gentlemen who take part in amateur theatricals, and who have hitherto been at a disadvantage in lacking the proper surroundings for photographing them in character. Here, however, we have a complete stage, with elegantly enriched proscenium, and all the usual accessories of a theatre. The stage is 'raked' in a regular theatre, and it is capable of accommodating companies of thirty-five or more in number for photographing in one group, while the scenes are brilliantly illuminated by electricity both from spotlights and 'fies,' as well as by a globular reflector, which is one of the largest ever used in a photographic gallery. Amateur dramatic societies will here find an opportunity for securing souvenir photographs of their various performances, as every resource of our establishment is placed at their disposal.

"Van der Weyde" Negatives.

"Our clients will be interested in learning that we have become possessed, through purchase, of 40,000 or more of the celebrated negatives of the well-known Regent Street photographer, Mr. Van der Weyde."

WE have received the thirty-first annual issue of "Willing's Press Guide," published by Messrs. James Willing, jun., 125, Strand, London, W.C.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JAN. 7th.—Mr. R. Beckett in the chair. Dr. von Rohr's veran, an instrument for correcting the apparent distortion of short-focus lenses was exhibited. Mr. Mackie read a letter in the BRITISH JOURNAL OF PHOTOGRAPHY, in which the writer advocated the use of barium chloride as a hypo eliminator, claiming a great saving of water, with permanency of result. Mr. Mackie had grave doubts about the method, and Mr. Haddon said that the writer had ignored the fact that the insoluble precipitate was formed not only on the print, but within the paper, and although it could be got rid of on the surface by swabbing, the precipitate would remain in the paper, and must lead to disaster. Mr. Haddon and the Chairman were of opinion that thorough fixation in fresh hypo, and fresh water, would give more permanent results than any other method. The addition of ammonia to the fixing bath was discussed, but Mr. Haddon pointed out that such addition, whilst useful for albumen prints, was not required with P.O.P., because it softened the gelatine, rendering a hardening bath. This led to a discussion on the difference between alum and formaldehyde for hardening prints—taken part in by Messrs. Haddon, Kindon, Mackie, and Drage.

CAMERA CLUB.

THE club met on Thursday, last week, for the first time since the Christmas recess, to hear a lecture by Mr. C. H. Bothamley on "Walled Towns in England." Although not a strictly photographic subject, this lecture formed a capital illustration of the useful way in which a camera may be employed in the hands of an observant and cultured investigator. Mr. Bothamley has a strong leaning towards antiquarian research, and in former lectures given at the club he has dealt with such subjects as the castles and the fortified houses of Britain. Each picture which he shows has been taken with the purpose of illustrating some particular feature of a building; some hole in a wall which gives the key to a problem, or some change of texture or material which is the line of separation between two different periods. It is not the least charm of the lecturer's method that he speaks without notes and in quite a conversational manner.

He said that there are in this country comparatively few remains belonging to the Roman occupation, so far as walled towns are concerned. Such towns were thus defended generally some time after the Norman Conquest, when the defence of the community became a more important factor than that of the individual. This became still more developed as the feudal system gradually died away. We have comparatively few fortified towns belonging to the Norman period. If we wanted to study Roman methods of defence we must turn to the pages of Caesar, of Tacitus, and must look for illustrations to the sculptures on Trajan's Column. The Romans fortified largely with earth

mounds—wood and trees, stones, earth, and sods. Of course little trace remained of such perishable things.

In the West of England, near Weston-super-Mare, there was the remains of a walled camp. At Colchester there were also remains of the wall which at one time enclosed the town. This wall was distinctly of Roman type, for it exhibited alternate layers of flint and red bricks or tiles, together with the intensely hard mortar which characterised Roman workmanship. It owed its defensive value entirely to its great thickness and strength. This wall was intersected with a tower, which some vandal had crowned with a pointed thatched roof, while a modern window had been pierced at one side. This terrible anachronism was equivalent to meeting Julius Caesar in Pall Mall adorned with a silk hat and an eyeglass. Colchester is the most complete Roman town which we now have; the only one of real importance.

A glance at the earthen walls of Wareham, in Dorsetshire, served to illustrate the way in which the Britons, after the departure of the Romans, still used Roman methods of defence without their skill in the employment of stone. These mounds were most probably crowned at one time with a wooden stockade.

The lecturer then proceeded to show a series of most interesting examples of walls from the towns of Yarmouth and King's Lynn. The latter town is the only one which retains its ditch in a still wet condition. Next Southampton was dealt with. This town was fortified from very early times because of its proximity to the Channel. Oxford next came under review, and a number of fine pictures which well illustrated the elaborate fortifications of Conway followed.

York is another town where the walls have been carefully preserved, and in some excellent photographs Mr. Bothamley showed how they were connected with the city gates. At one of these gates the portcullis can still be seen, with the machinery in a chamber above by which it was raised and lowered. Berwick-on-Tweed was the last town the walls of which the lecturer described. Here we had a later style of work, showing the influence wrought by the introduction of artillery. The gates, instead of being showy structures intended to impress the minds of those who came to attack, were inconspicuous—mere tunnels through the walls. Much money was lavished on the defences of Berwick during the reign of Elizabeth, for it was at that time one of the principal ports in the kingdom. In concluding his lecture Mr. Bothamley said that it was a matter of great interest to him to trace the gradual evolution of various means of defence through the medium of these walled towns, and he trusted that his hearers would have found it equally interesting.

After a few words from Mr. Middleton, who occupied the chair, the meeting closed with a hearty vote of thanks to the lecturer.

STEREOSCOPIC CLUB.

JAN. 11.—Mr. C. J. Williams, referring to the comments of "Free Lance" in the *BRITISH JOURNAL OF PHOTOGRAPHY*, last month, on his remarks upon the backing of plates being hardly worth the mess and trouble as a preventive of halation, said that had he been more fully reported "Free Lance" would have known the kind of backing medium he had used. Of course, there were no advocates for a backing that was not in optical contact with the glass, and the medium he had used in his experiments was glycerine and lampblack and Canada balsam and lampblack, and what he did say was that, after backing one half of many stereoscopic plates—leaving the other side unbacked—and exposing these plates to interiors with in most cases the extremes of light and shade, that in the finished negatives no improvement was perceptible in the backed over the unbacked end of the plate.

The case cited by "Free Lance," where his friend rigged up special arrangements in a studio for comparative experiments, was, in his own opinion, no test at all. The black velvet was represented by clear glass in the negative, because it reflected practically no light, and the window was the only thing to develop for. As soon as this was out in the development there was nothing else to develop for, and the thing was at an end. Then, again, in wet collodion, too, the development would be completed in a few seconds, with the image on the surface—not in the film, as with gelatine bromide—and in such circumstances far less chance for halation. He did not say that backing plates was absolutely worthless. What he intended to convey was that, with the good quality of plates procurable at

the present time for ordinary subjects, backing was not worth the trouble, and that, even in the most severe cases, he believed double or triple coated plates were far better than any single-coated plate with any kind of backing.

The Hon. Secretary said that when any member wished to be reported verbatim he ought to write his remarks on paper. Of course in a discussion it was not convenient, nor was it necessary, even if the report did not always embrace the whole of what transpired at some photographic meetings, it was, at any rate, not a loss to the readers of photographic papers. He did not see the object of reporting a meeting when the members had not anything of general interest to communicate. Somebody said once that the regular monthly reports of meetings helped to keep a society together," and the best he could say for such a society was that it was sorry for it. Mr. B. Bond thought that the old practice of reading papers at photographic meetings had become a thing of the past from the fact that so much of the commercial element was introduced into the proceedings by many firms sending their representatives to advertise their goods in the form of a "paper" or "lecture," that very many firms were willing at any time to respond to the call of the honorary secretary for something to show at the next meeting. He was not sure that the practice was altogether badly carried too far.

Mr. W. I. Chadwick exhibited a number of stereoscopic transparencies by stereoscopes conveniently arranged, with suitable lights on the table behind the stereoscopes. All the pictures were coloured or tinted, but so modestly coloured that many members did not notice the colouring until, after handling the slides, the colour was observed on the ground glass at the back of the slides.

Mr. Chadwick dissected two of these slides to show the colouring and next proceeded to colour the ground-glass backing for a transparency he had printed during the afternoon. The transparency is held in the left hand, with the film side in front—towards the observer. The ground glass is now laid in front, with the ground side out. The subject of the picture was thatched cottages in Devonshire. First some burnt sienna oil colour squeezed out of a tube applied by a piece of cotton rag stretched over the finger to the corners of the cottages in dabs or smudges. Then some green oil colour applied in a similar manner to the trees; the foreground, being a white road, was darkened by a few dabs of ivory black, both of the ground glass being treated in a similar manner for the pictures, the transparency behind the ground glass being the ground for applying the oil colours, and, as was shown, no particular care seemed to be necessary, for it did not take Mr. Chadwick longer to do this than it will take the reader to read this.

The ground glass was next removed to a pad of old newspaper on the table, and, as was said, all this mess has now to be removed and in the cleaning of the surplus colour sufficient can be rubbed into the ground surface to give the effect. It will be difficult with a piece of cotton rag to remove all the colour, but if the colour has got on the wrong place—"overshot the mark"—it can be instantly removed by a drop of ether applied by a clean piece of rag. The ground glass is now applied to the back of the slide, a paper mount and cover glass in front, and the slide is ready for binding in the ordinary way. Mr. Chadwick coloured two slides and made them ready for binding in about twelve to fourteen minutes. It is sometimes difficult to get rid of the "snowiness" in stereoscopic slides, say, an ivy-covered cottage—but by adopting this very simple method what would otherwise be a very inferior slide is very much improved. Of course, when the slide is much under-exposed the best plan is to make another, and to allow the colouring or tinting to be sufficient for the high lights, and not to show them as "coloured" slides, but to let the observer find that out for himself—which, when properly done, they do not often do. Several members exhibited stereoscopic transparencies, etc.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, on Friday, January 8, 1904. Present:—Messrs. H. Walter Barnard, F. A. Bridge, Alfred Ellis, W. Grove, Martin Jacobette, P. Lankes, Louis Langier, A. Mackie, Edgar Scamell, Lang Sims, and T. Turner. Mr. Alfred Ellis, president, in the chair. The hon. secretary reported the gift to the association of a bound copy of the *British*

Journal Almanac from the Editor, and was directed to return thanks for the same. Applications were considered from members requiring advice or assistance in legal and other matters connected with business, and they were of such a nature that no particulars can be given of them without disclosing matters which in the applicant's interests it would be undesirable to disclose for the moment. The President presented a pair of specially cut dies for striking a medal or badge for the use of the association, and a very hearty vote of thanks was accorded for the gift. Mr. T. C. Turner, hon. secretary of the Hull branch, made an exhaustive report of the action that had been taken in Hull to combat the "Oxo" free enlargement scheme, and stated that the Hull branch, which practically included all the photographers in Hull, had been successful in causing the specimens to be withdrawn from every shop window in Hull, and that they had enlisted the sympathies of the strict Grocers' Association, who had on their own account protested the Liebig Company against the system of advertising adopted. On the proposal of Mr. Martin Jacolotte, the hon. secretary was instructed to write a letter to the Hull Branch complimenting them on their energy, and congratulating them upon their success.

Arrangements were made for meetings of the "Derby Exhibition" and the "Examination of Assistants" sub-committees. Mr. J. C. Turner, at the solicitation of the president, agreed to open a discussion at the next members' meeting, to be held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, February 12th.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—HULL DISTRICT BRANCH.

At a meeting held January 6th, Mr. W. Barry in the chair, the Hon. Secretary reported upon the action taken by the branch at the close of last year in opposing the "Oxo Free Enlargement" scheme, and said that the members had every reason to congratulate themselves on their campaign, for not only had the specimen portraits absolutely vanished from their own district, but the effect of the opposition in Hull seemed to be far reaching, and probably photographers in other parts of the country would be benefited.

The members were under a deep obligation to the Editor of the *BRITISH JOURNAL OF PHOTOGRAPHY*, for it was obvious that the publication of the report of the October meeting, and the circulation of copies among the provision dealers, directly, and largely, contributed to the satisfactory ending of the trouble.

As decided upon by the last meeting, a copy of the *BRITISH JOURNAL* had been sent to the "Hull Retail Grocers' Association," and the reply received from the Secretary was as follows:—

HULL RETAIL GROCERS' ASSOCIATION.

1, Pottergate, Hull, November 19th, 1903.

DEAR SIR,—Your letter of the 11th inst., addressed to the President of this Association, was laid before a general meeting of members held Tuesday evening last, and I am requested to say that we deprecate most strongly the methods adopted by the Liebig Company in connection with the sale of Oxo. As an Association, we have all along opposed the system of present giving, which is certainly not according to the methods of trading advocated by members of this Association. You will therefore readily understand that we strongly resent any attempt on the part of manufacturers to resuscitate a system of trading, which, to say the least, does not add to the dignity of the trade. We are sending a letter of protest to the Liebig Company on the matter.—Yours truly,

J. ATKINSON, Secretary.

It would be probable that this protest, coming from an influential trade Association, would have no small effect upon the proprietors of "Oxo," and would doubtless induce the managers to re-consider their policy of interfering with the business of photographers. The Chairman proposed:—

"That a letter of cordial thanks be sent to the 'Hull Retail Grocers' Association' for its sympathetic attitude towards Hull professional photographers, for its opposition to the so-called 'free' enlargement advertisements, and for its letter of protest to the Liebig Company."

This was seconded by Mr. Boak (Driffild), and carried unanimously. Mr. Barry read the "Modern Society" advertisement of "Bromide Enlargements, surpassing anything in photographic enlargements that has ever been offered by any newspaper. A distinct departure in modern journalism."

In correspondence between himself and the Newspaper Manager, the latter wrote: "I assure you they are well worth the money (4s. 6d.);

moreover, one of our folks has been over the works and seen the machinery at work. Everything is done automatically, except the touching up." The letter concludes: "I write this explanation to prove that there is not the faintest suspicion of a swindle in it, or we should not accept the advertisement." Mr. Barry said that this proved that the "automatically" produced enlargement was not a newspaper enterprise, in spite of the advertised description, but it was a pity that pages of the Press were given up to advertisers, who, if successful, would gradually reduce the professional photographer to the position of a mere negative producer, and flood the country with cheap and nasty enlargements which might be made artistically and well for a little more money by the men who originated the portraits. The meeting then proceeded to discuss a plan for combatting the move in the direction of "sixpenny" photography.

Commercial & Legal Intelligence

At the Sheffield County Court, on January 8th, before his Honour Judge Mansel-Jones, the Provincial Advertising Company, 64, Westbar, Sheffield, sued C. Lindon, photographer, 173a, High Street, Ryde, Isle of Wight, for £1 12s., the balance of a year's rent in an advertisement cabinet; and W. J. Delicati, farmer, of Newport Street, Ryde, for £2 2s. Judgment for the plaintiffs in each case.

W. L. PARKINSON, Ltd.—This company has been registered with a capital of £2,000, in £1 shares. Object—To adopt an agreement with W. L. Parkinson the liquidator thereof, to take over the business carried on by the said old company, at 62, Dale Street, Liverpool, and to carry on the business of photographic mount manufacturers and merchants, manufacturers of and dealers in photographic materials and goods, printers, lithographers, photographers, stationers, makers of electrical and optical goods, instruments, lanterns, and lantern accessories, etc. No initial public issue. The first directors are W. L. Parkinson and W. J. Cumpsty. Registered office, 62, Dale Street, Liverpool.

BRITISH PHOTO PAPER COMPANY, Ltd.—The above named company had been registered with a capital of £5,000, in £1 shares (2,000 Preference). Object—To adopt an agreement with B. J. Hall, R. Hubble, and O. Andersch, for the acquisition of the business of manufacturers of and dealers in sensitised paper and other materials used in photography, and to carry on the same and the business of photographers and lithographers, printers, manufacturers of and dealers in photographic paper, apparatus, chemicals, and other requisites, etc. No initial public issue. The first directors (to number not less than two nor more than five) are B. J. Halk (chairman), R. Hubble, and O. Andersch. Qualification, £500. Remuneration not more than three guineas per board or general meeting, divisible (subject to any agreement). Registered office, Guilford Street, York Road, Lambeth, S.E.

RE CHARLES JOSEPH JONES, photographer, 75, Essex Road, Islington, N.—The first meeting of the creditors interested hereunder took place at the London Bankruptcy Court on the 13th inst., under the presidency of Mr. Chapman, Official Receiver. It appeared that the debtor commenced business as a photographer in 1892, at 75, Essex Road, Islington. He had at the time a capital of £30 of his own. The fitting up of the premises only cost £3 or £4, to make them suitable for his business. He carried on business successfully until about two years ago, when, owing to his inability to attend to it through illness, his trade fell off, and for some time past the expenses had actually exceeded the profits of the business. In addition to that he was obliged to draw heavier than usual from the business owing to the illness of himself and family. About three months ago he was pressed by creditors, and it was then that he realised that he was in financial difficulties. He was sued by the petitioning creditor, who obtained judgment against him for £119, and as a result debtor consulted his solicitor, with the result that on November 23rd last he called his creditors together and made an offer of 10s. in the £, payable by bills. The offer was accepted by most of the creditors, but owing to some of them standing out the matter fell through. Prior to the private meeting he executed a deed of assignment in favour of Mr. Cooper, of 271, Upper Street, Islington, N., a large creditor, but nothing was done under the deed of assignment, and it was not even registered. A statement of affairs was presented to that meeting show-

ing liabilities amounting to £700 and assets estimated to produce £100. Debtor alleged his failure to have been caused through losses on trading through illness and bad trading generally during the past two years. The summary of accounts showed gross liabilities amounting to £744 19s. 11d., of which £54 was due to fully secured creditors, the value of the securities being valued at £62, thus showing a surplus of £8, which is carried out as an asset. The unsecured liabilities were returned at £661 8s. 4d., and the assets, which consisted of trade fixtures, fittings, etc., valued at £15, and surplus from securities in the hands of fully secured creditors. Eight pounds was claimed by preferential creditors, so that there were no free assets, and the deficiency amounted to £661 8s. 4d. After the Official Receiver had dealt with a number of proofs of debt, he stated that debtor had no offer of composition to lay before the meeting; therefore he had been adjudicated bankrupt. After some discussion it was resolved to leave the estate in the hands of the Official Receiver for summary administration in the usual manner.

News and Notes.

ROYAL Photographic Society.—At the Lantern Meeting, on Tuesday, January 19th, at 66, Russell Square, at 8 p.m., the subject will be, "Camera Notes on Natural History," by Mr. Douglas English, B.A.

MESSRS. LAMBERT WESTON AND SON, photographers, of 23, Sandgate Road, Folkestone, are shortly opening a London branch of their business at New Bond Street, W.

MESSRS. JOHN WISDEN AND CO., of 21, Cranbourne Street, Leicester Square, London, W., have favoured us with a copy of John Wisden's Cricketer's Almanac for 1904. Extending to some 500 pages, it is full of matter of deep interest to all lovers of England's national game.

The Camera Club.—It is a matter of satisfaction to the honorary secretary, and will doubtless also be to the members, that he has been able to commence the year well, inasmuch as our next eleven lecture evenings have been arranged for, and will show that, in variety and interest of the subjects introduced, such a selection has probably seldom before been submitted to the members. The title of the lecture on Monday, January 18th, "The Romance of Swordsmanship," speaks very nearly for itself. Mr. Egerton Castle is well known as an author and playwright and is one of the greatest authorities upon the subject. He promises to show a variety of weapons used at different periods, and not only to show them, but also to demonstrate the manner in which they were used. Through our member, Mr. Haydn Harrison, and the courtesy of Mr. Bellfield, the chief representative of the Westinghouse Electrical Company, we are able to announce a lecture upon one of the most recent inventions—the "Mercury Vapour Lamp"—which we understand is capable of producing a greater amount of actinic rays than any light that has hitherto been discovered. This should prove a subject of great interest to scientists and also photographers. It is granted on all sides that our knowledge of electricity is most elementary. It is probable, therefore, that the photographs of electrical phenomena taken by Dr. Rodman will be a great attraction to us all, more especially to those who are interested in this subject. Twenty-four years' experience in Fiji as a Government official, and now as Receiver-General and Assistant-Colonial Secretary, have made the Hon. W. L. Allardyce, C.M.G., a great authority on the history of the Island and its inhabitants, as well as of their manners and customs. These he will describe, and also tell us of the renowned fire-walking ordeals. His lecture will be illustrated by slides. On February 1st, Mr. Nelson K. Cherrill will introduce a newly-invented form of printing frame, giving very great and hitherto unattained advantages in securing control in photographic printing. Without at the present time entering into any description of his invention, we may say that, inasmuch as the Berlin Patent Office has accepted his specification without a single modification or objection, it is certain that the invention is new, it being well known that the research made by the German authorities before granting a patent is of a most exhaustive character, and of far greater value, as a guarantee of its originality, than can be claimed for a patent granted in our own country.—"Camera Club Journal."

Correspondence.

PHOTOGRAPHIC WASHING.

To the Editors.

Gentlemen,—I have just read the letter from Mr. John Noton of your issue of the 1st. It appears to me to embody some slight error and to call for some explanation. Ba 2 (S₂O₃) is not the formula for barium sulphate which is BaSO₄, nor of barium thiosulphate, which is BaS₂O₃. If barium chloride solution be added to sodium thiosulphate the barium thiosulphate is perfectly soluble in water, and any precipitate is due to sodium sulphate or sulphite present. Does Mr. Noton's fixing bath contain sulphite?

I can see no way by which barium chloride can assist the elimination of hypo, and should be interested in an explanation from Mr. Noton as to the cause of his precipitate on the film surface.—I enclose my card, and remain, yours sincerely,

January 9th, 1904.

To the Editors.

Gentlemen,—The thanks of your readers are due to Mr. Noton for his interesting application of barium chloride for "hypo" decomposition. I perceive an error in his chemical equation, which should read Na₂S₂O₃ . 5Aq + BaCl₂ = 2NaCl + barium hyposulphite BaS₂O₃ . H₂O + Aq.

The acidulous radical of sodium thiosulphate, and the basylous radical of barium are bivalents, consequently they satisfy each other. This is, however, only a detail, and my purpose in trespassing on your space is to point out the danger of the practically insoluble barium hyposulphite in the film, which is not so easily swabbed off as imagined.

A better substitute for the purpose would be any of the safe, powerful oxidising agents, as the percarbonates and periodates of potassium which would convert the sodium thiosulphate into the harmless soluble sodium sulphate, and not merely effect an interchange of acidulous radicals. For negatives, I strongly recommend the bichromate salts, preferably potassium bichromate, which, besides effecting the complete oxidation of the hyposulphite of sodium into the sulphate, clears slight organic stains, and has a perfect hardening effect on the negative. 5 per cent. solution slightly acidified is a convenient strength, and two minutes the normal duration to effect the operation.—I am, gentlemen, yours obediently,

FRED. W. EDWARDS.

Swadlincote, Burton-on-Trent.

To the Editors.

Gentlemen,—Obviously, from the date, the letter in your issue of the 1st inst., on the above subject by Mr. John Noton, was written after the usual Christmas festivities, therefore we may excuse certain obscurities in style, but this will hardly excuse chemical errors.

In the first place Mr. Noton gives us an equation which shows the formation of barium hyposulphite, and then proceeds to tell us that the result of this equation is the formation of barium sulphate, besides both sides of his equation do not balance. It is some years since I learned chemistry, but I have not yet forgotten the elements nor elementary principles. Perhaps your correspondent will explain what becomes of the other molecule of Na, and how barium sulphate is formed from Ba 2 (S₂O₃), and where he gets his 2 (S₂O₃) from.

However, what I want to know is what he means by "photos;" are these negatives, or prints, or what, and what becomes of the hypo in the image-bearing film? Besides, gentlemen, I always thought that there was some hyposulphite of silver left in the film, and if I am right what becomes of the silver? Does it form silver chloride; if so are the "photos" going to be permanent?

Will Mr. Noton kindly enlighten my ignorance.—I am, yours, etc.,

January 9th, 1904.

CHEMISTS.

To the Editors.

Gentlemen,—In common, no doubt with many of your readers, I have been expecting some remarks upon the hypo-eliminating process

of Mr. Noton, as published in your issue of January 1st. To begin with his equation, which is open to some criticism, shows the formation of barium thiosulphate (hyposulphate), and *not* sulphate, and it seems very unlikely that this latter salt should be formed under the conditions given. Perhaps Mr. Noton, or some other expert, will throw a little light upon this problem.—I am, yours, etc.,
Ipswich, January 11th, 1904. J. C. WIGGIN.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—My attention has been directed to a notice in the last issue of your valuable paper, inviting "every person interested in orthochromatic photography" to study a lecture by Messrs. Newton and Bull, and as I expect wide publicity for their statements, which refer to the speed of various orthochromatic plates and emulsions, I feel compelled to take exception to at least those parts of the lecture, which personally concern the collodion emulsion and sensitiser "C."

Having introduced this sensitiser, the base of which has been discovered by Prof. Dr. Valenta, I have been in a position to make numerous spectroscopic and general speed tests, and as my acquaintance with this preparation is a long and intimate one I trust the lecturers will consider this protest as coming from the right quarter.

The figures I chiefly object to are:—

Collodion emulsion without sensitiser speed number, 14,000.

Collodion emulsion with sensitiser "A"—speed number, 21.

Collodion emulsion with sensitiser "C"—speed number, 480.

Now every operator whom I had the pleasure to teach the use of these preparations for trichromatic work and every teacher of collodion emulsion processes here and abroad, with the exception of the lecturers, will confirm my statement that sensitiser "C" produces practically the same speed as "A" sensitiser, and if Ag. No.3 bath is used before exposure gives a considerably higher speed. Direct 3 colour half-tone work, a now commercial process would be an impossibility if the blue plate required twenty times the exposure of the previous one, the ratio of exposure being 1:0.5:1½ or 2 for yellow, red and blue respectively.

I have submitted my objections to the lecturers shortly after reading the paper, and enclosed speed tests made with Chapman Jones sensitometer*, and expect that a misprint is responsible for the speed number 480. And further that Messrs. Bull and Newton will correct their statements, which have caused considerable comment.

If they however refuse to acknowledge the correctness of my tests I am prepared to submit the preparation to an independent authority, and to back my statements with the experience of a considerable number of scientific and practical men.

Thanking you in anticipation for the insertion of this letter, which may open a desirable discussion on the speed of orthochromatic emulsions.—I am, dear Sir, yours obediently,

HENRY OSCAR KLEIN.

9, Upper Brighton Terrace, Surbiton,
January 8th, 1904.

PHOTOGRAPHIC JUDGING.

To the Editors.

Gentlemen,—As a keen observer of technical and artistic photography, may I be allowed to point out that which I consider not fair on the part of the judges at photographic exhibitions and the like. I have visited a good few photographic exhibitions in my time, and as an expert in every branch of photography I have made it my duty after the awards have been made to go round and compare those pictures that have not secured an award with those that have secured a medal or certificate, and to my surprise what have I found not only in one case but many? For instance, Class 1 landscape or seascape. In the first place I have found a technically good and artistically well-arranged seascape, which was by far well deserving of the medal or certificate had been passed unheeded. Then we come to a landscape, the arranging of which clearly denotes that of the amateur pure and simple, not only has the picture this fault but we can clearly see by the picture that there has been carelessness in the manipulation of the finished print, such as air bells on the surface, and being unevenly developed in the shadows, this kind of

picture is awarded a medal, while the picture such as that above described we might as well say is not classified. Why judges betray themselves by making awards to such pictures I cannot understand be it favouritism, recommendation, or otherwise, it certainly does not reflect much credit on the part of the judges. But I am almost certain that in a great many cases that if the judging were left entirely to the judges there would not be many good medals wasted on bad pictures that we see at exhibitions. Moreover, by making awards to such pictures we can never expect to promote artistic photography or make a picture-maker out of the one or those who gain a medal or certificate on account of being a So-and-so in our society. Not only that, but it is apt to do the amateur more harm than good, for in time to come it is almost certain to fill him up with enthusiastic or imaginary ideas, and being a medallist without the slightest knowledge of a technically good picture, would no doubt make an application for a situation. Consequently on being asked to make a dozen prints from a cabinet negative or 15 x 12 negative on bromide or platinum the man would be almost certain to put his foot in it by not being able to make two prints alike, therefore it is to be hoped that those who have the honour of being judges will consider the harm they do by not awarding the medals to those who are deserving of them.—Yours, etc.,
January 5th, 1904.

GIVE CREDIT WHERE DUE.

JAN SZCZEPANIK.

To the Editors.

Gentlemen,—I think the note in your issue of January 8th does Herr Szczepanik a great injustice, and it is only fair to point out that I have myself been able to examine very minutely Herr Szczepanik's inventions, and, having also come personally into contact with him, I must say your paragraph gives an impression of him and of his work which is totally undeserved. He is a most unassuming man, and, so far as I can judge, has claimed no more than he has accomplished or can accomplish. He is a man of considerable scientific attainments, especially in optics, mechanics, and electricity; and the apparatus designed by him which I have had the opportunity of examining shows great originality and inventiveness. His weaving process, which I have seen in operation in Bradford, has met with the approval of Professor Beaumont and prominent practical manufacturers in Bradford, and it has been working there successfully for some months past. As to his process of colour-photography, I may say that I have seen and handled his extremely ingenious camera, by which he secures three images with one lens on one plate at one exposure, and have made numerous exposures with his special paper, by which brilliant coloured images are secured by a process of exposure which is no more difficult than printing a piece of P.O.P., and of which I have a number of excellent results. Dr. Neuhäus's opinion is rather vitiated by the fact that he has a rival process of his own to exploit, but which, so far as I have seen, yields nothing like such brilliant results as Szczepanik's. The latter has been highly complimented by Herr Worel, whose own process has figured considerably in the Continental photographic Press of late. Szczepanik's process has also secured the good opinion of Baron von Hübner, whose reputation as an authority on three-colour photography is beyond question. In the face of these facts, the statements which you publish are maliciously unjust, and can only have been disseminated by some one maliciously endeavouring to injure the reputation of the inventor. I cannot speak so positively about his telestroscope, but I questioned him about it, and gathered that models were in existence in Vienna, but that it had to be laid aside during the development of his other inventions which had greater commercial applications, and also on account of his having to perform three years' military service by the conscription laws of his native country. The sale of the plant for his weaving process refers, I have heard, to a duplicate plant set up in Germany, and the failure is due to some company-promoting operations of a character not unknown in this country. So far as the plant in Vienna and in Bradford is concerned, I have the best reasons for knowing that both are in active operation. I am holding no brief for Szczepanik, but feel that these facts, which are known to me, ought to be stated, in fairness to a man who is earnestly trying to widen the applications of photography.—Yours very truly,

WILLIAM GAMBLE.

January 11th, 1904.

* And precisely same emulsion and sensitiser they experimented with.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- H. E. SAWYER, 28, Broadway, Maidstone. Photograph of the late Rev. S. Joy
Photograph of the late J. P. Plomley
- E. HULTON & CO., Limited, Withy Grove, Manchester. Photograph of Miss C. Pankhurst.
- G. A. HALE, 25, The Borough, Farnham, Surrey. Photograph of the Bishop of Winchester.
- J. G. GOGGHE.—Better address Messrs. Kodak, Ltd., 43, Clerkenwell Road, London, E.C.

REDUCING.—STOPIA asks: "Will you, please, tell me of something—non-poisonous—which can be applied locally, to reduce the density or hardness of (1) Negatives; (2) Silver prints; (3) Name books on retouching other than the following:—Hewitt's, Johnston's, Bruce's, Drinkwater's, Young's, Photo Miniature." In reply: (1) Try a solution of persulphate of ammonia. (2) Silver prints are not worth the trouble of reducing. It is much less trouble to make fresh prints. Reduced prints are never satisfactory. (3) We do not know of any more.

PHOTOGRAPHS OF METAL.—C. E. BATES writes: "I herewith enclose a copy of directions for placing photographs on watch cases, etc. I have followed them out minutely but have not been altogether successful. Will you tell me if directions are correct, or, if not, can you tell me the correct and best way to do it?" In reply: In the abstract the directions seem fairly correct. If you refer to page 451 of our volume for 1901 you will find an article giving full working details for producing photographs on jewellery, etc. Better consult that, and we have little doubt you will find the cause of your failure.

PLATINUM TONING.—B. 2 says: "(1) I am trying a new sample of C.C. matte, which the makers say when toned in platinum only is quite permanent. Please say if this will be as permanent as if toned with gold first, as is usually done? (2) Will soft water (i.e., rain water) from a cistern dissolve the hypo out of prints and plates quicker than tap water, hard, and containing much lime? In reply: (1) Yes; quite as permanent. (2) Practically there is little, if any, difference. If you have a good supply of clean rain water you might use that in preference to the other.

STUDIO LIGHTING.—T. M. says: "I have got a conservatory I am about to turn into a studio. It is a single slant, glass roof right along and wall both sides. Length, 24ft.; width, 6ft. I have, of course, only a top light, and should be glad to know what blinds I should require, how to arrange same, etc. What light would be required to block out?" In reply: Without seeing the studio, or knowing anything of the height of the walls, we can give no information that would be of practical use. As you are a professional photographer, you are surely better able to see how to turn the studio to account than we, who have not seen it, possibly can.

ENLARGING.—AMATEUR IN EARNEST says: "Could you kindly give me the dimensions to make an enlarger similar to enclosed sketch to enlarge from cabinet to 15in. by 12in. (1) Length from small end to large end (outside). (2) Distance of lens from carrier. (3) Distance from lens to large end. (4) Size of largest end (inside). I can easily make it providing I get the

measurements." In reply: It is impossible to answer these questions as the focus of the lens to be used is not given. However, if you refer to page 1159 of the Almanac you will find a table that gives the distances required for any degree of enlargement, with any focus lens.

EMPLOYMENT.—J. D. (Aberdeen) says: "I am a young man who, three years ago, chose photography as my craft. In addition to my work in the studio, I am studying art and chemistry, in order that I may become a capable member of my profession. I am without money or influence, and from the advertisements in the various photographic papers, the prospects for future welfare do not seem at all bright, even though I should acquire considerable skill. Having written a young friend in New York asking him to make inquiries regarding the wages given to a young man there, he writes saying he has learned that an improver can earn, according to ability, from 8 to 10 dollars per week. A skilful man from 25 to 50 dollars per week. Will you kindly tell me if my friend's information is reliable? If not, what are the facts of the case, and, in your opinion, how do the prospects, all things being equal, compare in America, or any other country, with those at home?" In reply: Personally we do not know very much about the salaries paid in America, but we think your friend has over, rather than under, estimated them, though living is more expensive in the States than it is here, which, of course, makes a difference. We cannot say anything further.

FLASHLIGHT PHOTOGRAPHY.—D. M. S. writes: "I have got the chance of taking a flashlight photo of a dress rehearsal at one of the large London theatres, and I want to make the best of this opportunity. I should be deeply indebted to you if you would help me by answering the following questions. I will first mention what I have in the way of apparatus:—1-1 camera, triple extension. Lenses: Ross 8 by 5 Rapid Symmetrical; E. Suter, Aplanat A. No. 3, 12 by 10; both above are old lenses. Also a Goerz Double Anastigmat, 6in. focus. I understand this lens can be used for 1-1 plate. Questions:—(1) Which of the above lenses is the best to use? (2) If none of them suitable, what is the best lens to use, and where can it be hired? (3) What kind of flashlamp or apparatus is the best, cheapest, and most satisfactory? (4) How much magnesium powder would be required for any apparatus you may recommend? (5) Where is the best position in the theatre to take the photo from and place the flashlights. (6) How many lamps would be required? (7) What are the best plates to use? (8) Does it do to use any of the stage lighting, provided, of course, no naked light is seen by the camera? (9) Are there any firms where flashlamps or apparatus can be hired? If so, where?" In reply: (1) The Suter lens, as, being for 12 by 10, it will cover the whole plate better with its full aperture than the others. (2) Messrs. Sands and Hunter let apparatus on hire, but we think the one you have will answer. (3) Better consult the advertisement columns of the Almanac. There are many good forms advertised there. (4) It all depends upon the size of the stage. (5) Where the actors in their positions on the stage are best illuminated. The camera should, of course, be in the auditorium. (6) This must, of course, depend upon their power. (7) Any good rapid plates; and they should be backed. (8) Yes. (9) Possibly Sands and Hunter. As you appear to have had no experience in this direction, we should advise you to make some preliminary exposures in the theatre before attempting to take the group. We do not reply by post.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.
 ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION. Post Free.

(UNITED KINGDOM AND THE CHANNEL ISLES).

	s.	d.	
One Year	10	10	France, Belgium, United States, Canada, Australia, Africa, New Zealand, Newfoundland, Germany, Russia, Portugal, Spain, Italy, Egypt, India, China, Japan, &c. One Year ...
Half Year	5	5	18s.
Quarter Year	2	9	

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

EX CATHEDRA.

Novel Radiations. According to *Nature*, among the numerous special kinds of radiation recently discovered, not the least interesting are the *n*-rays of M. Blondlot. These rays, which were first discovered in the radiations from incandescent bodies, pass readily through glass, aluminium, black paper, and other bodies, but are arrested by lead or by moistened paper. The most convenient way to examine them is by means of their action upon feebly-illuminated incandescent bodies, the luminosity being increased when the Blondlot rays fall upon them. In a more recent paper M. Blondlot has found that bodies in a state of strain, such as tempered steel and unannealed glass, give off these rays spontaneously and continuously at ordinary temperatures. He anticipates that this effect may prove to be of the utmost importance in the case of nerves, for, though the interior anatomy of the body may be indicated, as far as the bones and some other structures are concerned, by the Röntgen rays, no external indications of nerves have hitherto been observed, and new studies of physiology and medicine are thus opened up. Whether or not these indications will be capable of being recorded by photography we are not yet in a position to state.

The Microscope as Optical Lantern. Many workers with the microscope, desirous of showing its revelations to the uninformed public, are often in despair at their apparent stupidity and inability to make proper

use of their eyes with regard to the instrument, and no doubt this is one of the causes that have made photography popular; but Mr. Walter Bagshaw, in *Nature Study*, has gone a step further, and, in lieu of actually producing the photograph, allows his audience to see the projection, either upon a piece of ground-glass or upon a special cardboard screen—upon a small scale goes without saying. One of the advantages of this mode of exposition is the possibility, which naturally does not exist in the ordinary photograph, of showing the objects in motion. He recommends very simple means for carrying out his plans. The microscope is placed in a horizontal position, and the image thrown upon a piece of white cardboard propped up with a few books. The microscope mirror is to be moved on one side, and the lamp and bull's-eye condenser placed so as to send parallel beams upon the slide. A disc of light will be seen on the cardboard, but will probably appear brighter in some parts than in others. Then just as a lantern light needs centring to get an even disc, so the bull's-eye and lamp may need a little to and fro alteration till the light on the disc is even and uniform. Centring the object and focussing are then all that is needed. He finds that if the sub-stage condenser and higher powers be used a sheet of ground-glass between light and sub-stage condenser will often make a wonderful difference in securing even illumination. He remarks that he has often shown an insect's head 12in. in diameter, and has heard microscopists express wonder that they have never thought of this simple method of exhibiting their slides.

Astronomical Photographs. Anyone who has been fortunate enough to hear a lecture from Sir Robert Ball will know well enough that he is a most lively occupant of the rostrum. He has lately been lecturing at Edinburgh, and one of the Scotch newspapers is moved to speak of his gifts as being racy, vivid, interesting, and instructive. From the same source we learn, with true gratification, that Sir Robert pays due regard to the part which photography has taken in advancing the work of the astronomer. Indeed he goes somewhat further than we ourselves should have ventured, for he said that photography has caused as great an advance in astronomy as did the invention of the telescope. This is high praise, indeed, but this is not all. He is also reported to have said that "the philosophical theory of Kant on the one hand and the mathematical theory of Laplace on the other—made almost contemporaneously in the eighteenth century, but quite independently—had been confirmed in the most striking way by the discoveries resulting from photographs of the heavens." Anyone who is so well equipped to give popular expositions on telescopic researches as is Sir Robert Ball has reason to bless photography for the beautiful illustrations it affords in the shape

of lantern pictures. How different are these to the terrible round spots on a surface of blue which had to suffice for the lecturers' needs in the old days. Sir Robert must himself remember the time not very long since when he had to depend for his illustrations on these things, for there was nothing better. But he carried it all off and hid the deficiencies of his pictures by some little joke at their expense which the audience keenly relished. In the same spirit poor Artemus Ward would cover the villanies of some of his own lecture illustrations. Everyone will remember how he said—"That is a horse, I have had a special message from the artist to say that it is a horse." But let not these considerations tempt the average lecturer to show bad pictures; it requires a genius to make the public swallow them.

* * *

The Radium Cult.

That radium has taken the world by storm is an undoubted fact; it is scarcely possible to take up a periodical of any kind, scientific or popular, without finding in its columns something remarkable about this wonderful substance. And well may this be so, for it is at once interesting to the general public from its visible singular properties, and to the man of science for its apparent upsetting of almost the very groundwork of modern conceptions of matter. It is not surprising, therefore, to learn that a new journal is to be started devoted to this subject alone; its birthplace is, suitably, Paris, and its name is to be *Le Radium*. It will appear monthly, and is to give the fullest and latest particulars concerning the development of M. Curie's mysterious discovery. The first number is to contain a special article giving full particulars of the scope of the journal and the possibilities of the wonderful substance that gives the title to the publication. This new periodical will be a desirable one from many points of view, not the least being the authentic nature that should attach to any of its own pronouncements, there being so many absurd and impossible stories about it already in circulation. We shall, in all probability, have trustworthy accounts of its photographic possibilities, our knowledge in that direction being at present rather hazy. As an example of the sort of thing that will pass through the alembic of the editorial mind may be instanced the statement published that Mr. E. H. Gage, of San Francisco, claims to have perfected a simple method of extracting radium from ore, and to have invented a small battery which, with one charge of a preparation of radium, will run a motor-car for three hundred miles; and again, of a different complexion from this the statement that Professor A. H. Phillips, Demonstrator of Physics and Mineralogy at Princetown University, has completed a series of experiments with minerals collected in the State of Utah, and that he declares he has succeeded in obtaining from twenty-five pounds of currolite a sample of radium, though not so powerful as the European production, its strength being 1,500, while that obtained from European ores is 7,000. Professor Phillips's samples, however, are, he states, sufficient for many practical purposes.

* * *

The Electric Lantern.

Now that the lantern season is upon us it may be well to refer to an important consideration with regard to the use with this popular instrument of the electric arc light. Every town of any importance has now its electric mains, and it is so usual to find private houses illuminated with glow lamps that one takes it quite as a matter of course. Public halls and lecture rooms are now commonly illuminated in the same way, and in many instances the necessary special leads have been connected with the main for the provision

of an arc light for the lantern. No better kind of illumination can be found for lantern use, provided that the carbon holder or regulator is of a good pattern, and that the operator knows his business. But there is one important condition of success, and that is, the current supplied must be of the continuous, not the alternating kind. Unfortunately for lantern workers the alternating current system is much more common than the other, because for general illumination it is all that can be desired, while it is more economical in first outlay. But it gives a poor kind of arc light at the best. It can be known at a glance in some of our thoroughfares by its faltering movement, its violet tinge, and the loud hum which it emits. These drawbacks become accentuated when the light is used for lantern projection, the variation in its intensity being most annoying, the violet band across the sheet irritating to the eye, and the loud hum on one note most distressing to the ear. If, therefore, our advice were asked with reference to the installation of the electric light for lantern use where the alternating current only is available, we should at once say "don't." A limelight of only average quality is much better in every way. But let it be distinctly understood that we have no sort of prejudice against the electric arc—in fact we prefer it to any other illuminant for the lantern, but it must owe its radiance to a continuous current machine, or still better, to a secondary battery. In certain cases we have known even the best light to show a little palpitation which has been traced to the action of the gas engine, which drove the dynamo machine. But when the current comes from a battery it is absolutely steady. We know well enough that this result cannot be brought about if the operator does not pay attention to the space distance between his carbons, and if the carbons themselves are of poor quality; but given these things and the light is the best procurable. It is an easy error to fall into to imagine that an electric arc light must afford more radiance than any other illuminants, and the assumption is to a certain extent true. But with the alternating current much of the available light is hidden between the carbons. With the other current one carbon becomes intensely luminous and it is possible to so turn it towards the lens that the whole radiance is thrown out towards the sheet. Unless these conditions can be secured the lime light is preferable for lantern use.

PROGRESS IN RESPECT OF PHOTOGRAPHIC PERMANENCY.

It is interesting in any art or science, and often instructive, to now and again refer back and see what was done in the long ago and compare it with what is being done at the present time. In nothing, perhaps, does this apply more than in photography, although it is but little over sixty years old. Only those of our older readers—and we are pleased to say they are many—who can hark back to the state of photography during the fifties and sixties and compare it with what now exists, can to the full realise the advantages the present-day workers, whether they be professional or amateur, possess over those of the earlier days of the art. Not only does this apply to processes and increased facilities for working them, but also to apparatus of every description. At the present time we obtain our plates ready for exposure in the camera instead of having to prepare them ourselves at the time they had to be used, whether in the studio or the field. Now we buy our paper ready for the printing frames, instead of having to sensitise it ourselves, even if not to salt or albumenise it. At the present time, owing to the improvements in lenses, there is no fear of getting curved marginal lines in our pictures, and our apparatus

generally is of the most portable kind and most convenient in use.

It is not our present intention to dilate on the troubles the earlier workers encountered, or the inconveniences under which they, perforce, had to work, but the fact remains that good work was done in those days, and much of it would put to shame some that is being turned out at the present time, more particularly when it is considered that at the period alluded to there was no retouching to assist the portraitist. But we need not enlarge further on this topic as our object in this article is to inquire whether the results, in every-day work, now are both as regards negatives and prints much, if any, superior, as regards stability, to those of the long ago, considering, at the same time, the better theoretical knowledge we now possess in this connection? Or, to put the question another way, are the results produced to-day as stable as those produced in the early days of the art, and if not, why not?

The first negatives made were on paper—calotypes. The paper was prepared with iodide of silver, developed with gallic acid, and fixed with hyposulphite of soda. Hundreds of these negatives are now in existence which are as good as when they were at first taken, notwithstanding that they are sixty or more years old, so are many of the prints made from them by what is practically the same process. If we take up an old family album containing portraits taken, say, during the *carte-de-visite* period we shall find, no doubt, some of the prints, which, of course, are on albumen paper, in a more or less faded condition; but we shall also find very many that are in an excellent state of preservation, and some as good, or nearly so, as at first, notwithstanding that they are forty or so years old. If we go through a more modern album, containing prints made within the last decade or so we shall, as a rule, find much the same state of affairs as in the older collection—some have changed badly, whilst others have not. It must be understood here that we do not include platinotypes or carbon pictures, but refer solely to silver prints. Now, as the fading action is a progressive one, we can well speculate on the state the pictures in the modern album will be found in by the time they reach the age of those in the older collection. The interesting point for consideration is whether this earlier fading in the modern work is due to the processes employed or to the manipulations, for there is no question that at the present time we know more about the theoretical part of the subject than we ever did before, but are we turning that knowledge to the practical account we might do?

From the early "fifties" till some thirty years later the collodion process was the only one used in practice for negatives, and the negatives then made show no signs of fading. In fact, we do not remember ever having seen a collodion negative that has in the slightest degree faded or become spotty from contact with damp paper. This is more than can be said with regard to gelatine negatives. So far as one can see there is no reason why gelatine negatives cannot be made in every respect as stable as collodion ones, but the fact remains that a very large proportion of them have not proved themselves to be so, as most photographers are aware. But is that simply a want of care in their production? If it is it does not redound to the credit of their producers.

At the present time the bromide paper is the one solely used for enlargements when they are made by a silver process, but many of those which have been made but a few years—even months in some instances—are already showing signs of decay by passing into the "sere and yellow" stage, though many of the early ones—those

made in the early days of the process—are as good as they were when they were first produced. This should show that it is not the process itself that is at fault, but the method of working it. In the early days of the art, and before the advent of bromide papers, all silver enlargements on paper were made on iodised paper by a method analogous to the old calotype process, and they have proved themselves to be exceedingly permanent, as have done the old calotype negatives.

Seeing that so large a number of silver pictures—negatives and positives—show such early signs of deterioration, while so many of those produced several decades ago remain intact, it becomes important to inquire whether we have in processes, or in the manipulation of them, profited to the extent we should from our present knowledge of the theoretical part of the subject of which at one time the earlier workers knew but very little about. At some future time we may recur to this subject and deal with the conditions prevailing in the processes of old and where they differ from those obtaining in the processes and methods of the present time.

SOME POINTS CONNECTED WITH LANDSCAPE THREE-COLOUR PHOTOGRAPHY.

[Being the Sixth Traill Taylor Memorial Lecture.]

I FEEL to-night that I am following illustrious lecturers, and can scarcely hope to arouse the same interest in the subject I have chosen as they aroused in theirs. However, the subject I have chosen is one which is of importance at the present day, and I make no apology for talking about it. Three-colour photography is a most interesting research, opening vistas in the future [which have most subjects of applied science], and I may say it calls for a study of pure science, which is difficult in parts, since it has to take into account physiological phenomena.

The main principles of three-colour photography are well known, but I doubt much whether anybody who has not studied it and tried it under varying conditions of light has ever fully realised how much remains to be done to simplify it, and make it thoroughly practicable in the hands of the practical photographer. It may be said, I think, with some truth, that up to the present time the main work done by it has been still-life, and the copying of pictures. It has been but little applied to portraiture (though under proper conditions this is not more difficult to undertake than still-life), or landscape work. It is in this last that difficulties arise which have not been encountered in other lines of photography. We have in it the old difficulties of wet-plate photography due to varying light and shade during exposure, and where three exposures are made for one picture the chances are that the conditions are not quite the same during each exposure. Then there are the subtle nuances of atmospheric effect which have to be rendered, together with the delicate and ever varying tint of the sky. The colours have to be very exact in order to please, and at the same time an artistic effect is much to be desired. The question arises—Can this be done?

The answer to this is that it can be done if the greatest scientific exactitude is exercised in every particular. In the first place it must be determined as to the light in which a picture has to be viewed. If it be for a print, there is no possible question about it that it must be good day-light, and if we choose day-light, it should be that mixture of sky-light and sunlight which is to be found in cloud-light, and which generally illuminates our rooms, when windows afford the entry for the light. We will therefore take it that for viewing a picture, the light to be used must be daylight of this

quality. It may appear that we are beginning at the wrong end of the subject; but this is not so. Because, before we can know how to produce prints, we must know what negatives are suitable, and before we know this we must know whether we can produce prints from them which will give the required accuracy. The only real test of the three negatives is when the prints are first produced in black and white, and the colour subsequently given to them. If a print is to be gauged on the depth of colour it takes, according to the fancy of the amateur printer, it must very seldom be correct, except by a lucky chance. When the shades are given by opacities through which the coloured lights have to penetrate, then there is likely to be truth in the result.

This points to the true test for colour negatives being the method of triple projection as devised by Ives, and I may say the more I have studied the subject the more I am convinced, that if a picture is produced correctly by this method, it is certainly a better guide for producing correct pictures than any other method. It is from this point of view that I have been working, and I think it will be found by others, as well as myself, that certain preliminary considerations are necessary.

I wish to introduce the subject by a simple experiment. I cannot do better than commence by throwing on a small screen the image of a coloured object, which must be correct, since it is formed by three spectrum colours. In the apparatus before you there is the power of throwing a patch of white or coloured light upon a screen. It is white when the whole spectrum

FIG. 1.

is combined, and it is coloured when a small portion of the spectrum passes through a slit at the front. In fact, we have an image of one surface of the prism thrown on the screen by the lens in front. If on the prism I were to throw an image of any object, through the slit of the spectroscope, which I have shown can be done readily, and is of use in photographing in monochromatic light such an object as the sun, we get on the screen an image in one colour according to the position of the slit in the spectrum. If, instead of throwing an image of the sun, we place a lantern slide with coloured glasses against the surface of the prism, we have an image of the slide. When we pass a slit through the spectrum we get the glasses shown in monochrome, some being bright or dark, according to the absorption of these glasses. If I place three slits in the spectrum, one in the red, one in the green, and one in the blue, which rays when combined form white light, we still have the same colours as before, but less bright, owing to a large part of the spectrum being cut off. If the

large lens is replaced by three lenses placed opposite the three slits we have three images of the small glass discs, one in red, one in green, and one in blue; and it is these three sets of images which is the aim of three-colour photography to reproduce. We can choose our correct colours, which are best represented by the sensation colours, from the white of sunlight by the mixture of the three, and so reproduce the colours of the glasses.

We first have to produce the three negatives which would produce the transparencies like those I have shown you, but unbacked by colour, for the colour is added afterwards. To do this, it is evident we must use screens or coloured media to cut off all unnecessary colours. To use the spectrum itself is, owing to the varied sensitiveness of the plates, almost impracticable. But the simplest way of doing this is to take coloured pigments and photograph them, under certain conditions. It is necessary to know how much of each of the three standard colours is necessary to make, when mixed, the colours of the pigments. Owing to the different brightnesses of the colours and the difference in composition it is better to arrange that all the colours for which (say) a red screen is sought, to have the same amount of red in them when photographed. If the negative shows equal densities when photographed through a red screen, it will show that the screen is correct; if not equal, the screen must be altered till it does. The screens must be selected by daylight exposure. In a paper I read before the Royal Photographic Society I showed how it was possible to prepare rotating coloured sectors which should be available for selection of screens for all kinds of plates. There is one difficulty in the sectors, and that is the method by which the luminosity and colour composition of the papers is arrived at. I wish to show you what I believe is a new plan by which not only the luminosity of the paper is arrived at, but also its composition in terms of the three colours used for projection. It is a very simple plan indeed, for it also tells us the spectrum colour which, mixed with white, is the colour of the screen. In the first place it is necessary to know the % composition of every spectrum colour in terms of the three spectrum colours which we have selected already, and if we know this we can readily find the components of the pigment colour in terms of these three projection colours. The diagram before you shows such % composition in terms of the colours which most nearly excite the three sensations.

FIG. 2.

In the original diagram of % composition in terms of the three sensations there is only one sensation which is excited by one colour, and that is the red; the other colours excite two, and even three, sensations in a more or less degree, but from this diagram I have calculated what the % is when the colours alone are used, and we get the diagram before us. I have left out the violet, for it is composed of red and blue, and has no place as a simple colour. This diagram is one of the starting points; the other is the luminosity of the spectrum with the inherent white deducted from its several parts. Suppose we wish to know all about this emerald-green paper, we proceed as follows:—

A colour patch of white-light is thrown on the screen, and in the path of the beam is placed a bundle of plain glass, which deflects part of it at an angle of 45 deg., and the rest passes through. The deflected beam is again reflected by a silvered mirror on to the screen, so that the patch formed by it is superposed over that formed by the direct beam. A rod in the path causes two strips of light to be placed side by side. In one of the strips of light is placed the coloured paper, and in the other white paper. A slit is placed in the spectrum to allow only one colour to fall on the two papers, and a rotating sector placed in one of the beams equalises the brightness, the relative brightness of the two white beams having previously been equalised.

By noting the apertures of the screens we find how much the coloured paper reflects in comparison with that reflected from the white paper, and so we proceed with all the different rays.

Knowing the luminosity of the rays in the spectrum of white-light, we are able to make a luminous value of the colour. We know the % composition of each ray, as already said, and we add all the red % together, and the green % and the blue %. We know that in white-light there is so much red, green, and blue. We take, say, the colour which will all be used up in making white and deduct the % of the two colours from what has been found, and we get a % remainder of two colours. We look at the diagram and find what colour has that % and it is that colour which matches the colour of the paper with the white light in it.

But we have also found the luminosity value of the colour of the paper, and, calling that of white 100, we have now the true luminosity of the colour of the paper. Again, as before said, we have the % composition of the colour of the paper in terms of the three colours, and that gives us all we want in making the sensitometer.

I will not go further into the matter of making the sensitometer, since that is fully described in the paper I have alluded to. The novelty lies in the calculation.

The sectors before you have been prepared in this way, and the screens for any brand of plate can be found on the principles I have enumerated, for one rotating sector contains equal amounts of red, another of green, and the third of blue. The photographs of these rotating sectors should show the rings all of equal density when the screens are correct.

Be it remarked that the exposures need not be through only one medium at a time. For instance, the screen for the red may be the exposure through red for a certain time, and through orange for a certain time, and this will make the simple colour to be judged.

Having found the screens, we have next to find the relative exposure to be given. I have here three screens which I have used. They were prepared by Mr. Sanger Shepherd with his sensitiser, and they are good for the Cadett spectrum plates. Roughly, for a Cadett spectrum plate the exposures through three screens were: red 4, green 2, blue 1. When a fresh batch of plates is taken into use, a plate is placed in a dark

slide with the screens in front, but in contact with this plate is placed a scale of gradation through which the light has to pass as well as through the three screens. A rotating cardboard sector is placed in front so that four times the light is admitted to the red, twice to the green, and three is admitted to the blue. The light used is the light coming through a small aperture in the wall of a dark-room, and it is light reflected either from the sun or from bright cloud light.

The exposures take place together, and the gradation enables one to find out any difference that exists in the supposed correct times of exposure. It may be noted that by placing three slits in front of the three screens, several exposures may be made on the same plate as a check. The densities of the negatives taken under the three screens can be measured, or prints taken and compared.

If the exposures were relatively 4, 2, 1, the densities of the negatives should all be the same. Having got these relative exposures, they should be rigidly adhered to, and the batch of plates tried. This method of testing may be carried out even after the plates have been used in the field when the relative times are correct.

We now come to the transparencies, and there is not much to say regarding them. They were taken in my case not by contact, as they are reductions, and they should not be too opaque, but like a good lantern slide, and be full of detail. If the relative exposures of the negatives have been correct, they should without any alteration or manipulation give an accurate colour picture on the screen. Now it has happened with myself that I have not been able before exposure exactly to gauge the colour sensitiveness of a particular batch of plates, and in the case in my mind the green received about $\frac{1}{4}$ too much exposure, according to the test I have shown. The green negative was therefore too dense, and the transparency slightly too light. A correction was made in the transparency by giving the green $\frac{1}{4}$ more exposure, with the result that the picture in colour was correct. It may be as well to say that the transparencies should be taken separately, so that the central rays of a lens are used, and the light should be the same for each. The results of some of these we shall see shortly in the triple lantern.

In cases where the slides can be of the same size as the original the prints may be made on bichromated gelatine, as in Sanger Shepherd's process, and dyed with suitable dyes so that their continuity may be good.

So far, with the exception of the method of Professor Woods, who used specially ruled tracery, it has been impracticable to reproduce on the screen or in the photochromoscope the images coloured with spectral light; but I propose to show you that this can be done in a fairly simple manner.

The slits in the spectroscopie are still in the positions which allow the three rays to pass which form by their mixture white-light. Suppose we place in the position occupied by the patches three condensers which are identical with those of the triple lantern. Then it is possible by spectrum lenses to produce a disc of white-light on a more distant screen. This is only possible by diverting the red and blue rays to one side by right-angle prisms, and reflecting them on to the outside condensers as in the diagram. When this disc is formed we can place in the proper places the transparencies made from the three-colour negatives, and, after focussing and adjusting, the three will blend together and we shall have the photograph in colour produced by spectral rays. Unfortunately, we do not get such a body of light as we do with the lantern, and in order to make a bright picture it has to be made fairly small.

There is one curious feature, however, about this. We may still have exactly the same proportions of the three colours and join the transparency at a greater distance, so that the picture

becomes larger, and it will at once be seen that the picture becomes less luminous and the image becomes green.

This is exactly what happens in moonlight. The white-light is reflected sunlight, and yet it appears green in the latter light. When all rays are much reduced in intensity the colour of the red just disappears, and that is the case in moonlight and in the transparency.

Every one has not this apparatus, and, indeed, for lantern projection on a large scale this method is at present impracticable, and so we fall back on a simple three-colour lens lantern, which suffices for all ordinary purposes. I have used simple lenses in its construction, as will be seen in the diagram. The lenses themselves cost but a few shillings, and the whole apparatus can be made by any one who desires it, in a simple way. The principles on which it is based are, of course, Ives'. It is used with the electric light, and by means of bundles of plain mirrors (which in this case are microscopic glass bound together), the beam coming through the condenser of an electric lantern is diverted right and left, and also proceeds centrally. Those to the right and left are caught by silvered mirrors, and the three parallel beams proceed to three secondary condensers in a line in front of which the transparencies can be placed, and the rays collected from thence by three other spectacle lenses which form their images on the screen, and which can be blended together. Behind the secondary condensers are placed respectively coloured absorbing media, such as glasses which transmit light which approximately the same as the colours which represent the three-colour sensations. The colours seen on the screen and the resulting colour may or may not be white-light. Now we come to an important part of the matter. The three colours can be so mixed that they do form white-light, which is of the same purity as that quality of daylight which I have already alluded to. This is done by throwing alongside the disc white daylight which can be reflected from an aperture leading from the outside of the laboratory, and the necessary alterations made by changing the number of the glasses till the mixture of red, blue, and green absolutely match. The final very fine adjustment can be made by placing in contact with one or other of the coloured glasses a piece of plain glass.

I may say that this takes some time to do, and, as daylight is fleeting, I have matched the light of day by my colour patch apparatus, and from this apparatus placed a patch of light of the right whiteness alongside the disc of light coming from the triple lantern. Such a disc of light is now before you, and it will be seen what a different colour it has to that of the arc light.

(Demonstrations were then given).

It will be noticed of course that if transparencies are illuminated with the three colours which make the white of the arc light, the nuances of colour in the landscape will be different. I felt that it would be interesting if the triple lantern pictures could be compared with the Sanger Shepherd process; and Mr. Sanger Shepherd kindly undertook to prepare from some of my negatives a set of lantern slides. I am of course not going into the process, as it is well known; but I may say that I was astonished at the results, which compare admirably with the slides I have shown you. We have, then, three distinct methods of testing the quality of the results, and if I may say so, I have a fourth, for on several occasions when I took colour pictures I sketched them in water-colours, and the results are satisfactory to myself and show a similarity in colour which is striking.

SIR W. DE W. ABNEY, C.B.; F.R.S.; D.C.I.

A NEW COLLODION EMULSION. I.

BARON VON HÜBL, in the current number of "Das Atelier des Photographen," gives the following method of preparing an emulsion suitable for process work, and he points out that the ordinary collodion emulsion, which possesses but a very low sensitiveness, is generally sensitised with a silver salt which increases the colour-sensitising action of any dye. The most generally used dyes are the silver salts of the eosine group, and these have the advantage of combining the action of the silver with that of the dye, without any tendency to fog. Dr. E. Albert uses these silver compounds in ammoniacal solution, either as an addition to the emulsion or for bathing the plate. Another method of colour-sensitising is to bathe the plate in a plain solution of dye, and then just before exposure to bathe in a very dilute silver nitrate solution. Hübl points out that, although faultless results can be obtained by these methods, the very presence of a soluble silver salt is the cause of innumerable troubles, such as comets, red fog, general fog, etc., and the character of the negatives leaves something to be desired, as they tend to hardness, and soot and whitewash are too often met with.

An emulsion would be free from all these troubles if it were possible to make one without soluble silver salts, and which should possess sufficient sensitiveness to be applicable to process work, and which could be sensitised by the addition of silver free dye solutions. Numerous experiments towards this end were made by Hübl in conjunction with Herr G. Winter, and although their experiments have not reached a final solution of the problem, they have arrived at a fairly satisfactory result which promises well. A dye can only sensitise when it stains the silver bromide itself, and every circumstance which increases this action, increases the sensitising and, on the contrary, everything that prevents this, lowers the colour sensitiveness.* Soluble bromides in the emulsion either reduce or prevent the coloration of the silver bromide molecules, and therefore all emulsions which have been prepared with excess of soluble bromide cannot be highly colour-sensitised. If the small trace of excess of bromide is removed by the addition of a small quantity of a silver salt, the dye colours the silver bromide, and the sensitiveness to a particular spectrum region appears. If a further addition of silver is made, it does not as a rule increase the action, but lowers it. It is only with those dyes which give an insoluble silver compound that an excess of silver gives an increased action, as then a more intense coloration of the silver bromide grain is caused.

Soluble chlorides in an emulsion, unlike bromides, exert no influence on the colour-sensitising, and therefore a bromide emulsion which contains some silver chloride is very suitable for the preparation of colour-sensitive plates, as there can be no excess of bromide, for this would be decomposed with the silver chloride and form silver bromide plus free soluble chloride. In order to prepare an emulsion with chloride of silver, it is only necessary to replace some of the bromide with chloride, and as long as the former is not in excess it seems immaterial how much of the latter is. In the presence of ammonia fine-grained and creamy pure bromide emulsions can be easily formed which may be diluted without trouble, but if an acid is present coarse-grained bromide of silver is readily formed. Ammoniacal emulsions are thus less likely to fog, and as Luppo-Cramer† has pointed out, a considerable quantity of ammonia may be added to a washed emulsion without fog being caused.

It is well known that ammonia causes a rapid ripening of

* Jahrbuch für Photographie, Eder's 1903, p. 128.

† Photogr. Corresp. 1903.

the bromide of silver, and the emulsion which, when examined by transmitted light, is first red and fine-grained, becomes grey and then blue and violet and distinctly crystalline in character, but this does not necessarily mean increase of speed, but too frequently fog. The ripening process, at any rate with collodion emulsion, only takes place with ammonia if free bromide is present, and if to a washed emulsion ammonia is added, the bromide remains red and the collodion becomes thin and is finally destroyed. As the silver bromide remains also unchanged in the presence of soluble chlorides, the experiments were directed towards the preparation of a chloro-bromide emulsion with ammonio-nitrate of silver, and actually a very fine-grained and tolerably sensitive emulsion was thus obtained, which contained silver chloride dissolved in ammonia, and excess of soluble chloride, and whilst it possesses the sensitiveness of an emulsion with silver excess, there is not the slightest tendency to fog.

The addition of a soluble silver salt does not increase the sensitiveness. If the sensitiveness of this emulsion is due to the silver chloride dissolved in ammonia, the addition of an acid would reduce the sensitiveness, but an addition of acetic acid has no effect, and therefore it would appear as though the bromide of silver was in a more highly sensitive state. To prepare the emulsion, three solutions should be made:—

(a) In a bottle, of 1,500 cc. capacity, make 700 cc. of 4 per cent. collodion, using two-thirds alcohol and one-third ether as the solvent.

(b) The silver solution is made by adding to 50 g. of melted silver nitrate, 50 cc. of ammonia sp. gr. 0.91, and if the solution is not quite clear a little more ammonia must be added. Then 100 cc. of 95 per cent. alcohol should be added, and when cooled down, if there is any silver thrown out of the solution, a little water, from 3 to 10 cc., should be added till the crystals are dissolved. This solution should not be filtered.

(c) The bromide solution: 27 g. of dry ammonium bromide should be accurately weighed and placed in a flask and covered with 40 cc. of distilled water, and heated till dissolved. Then add 100 cc. of alcohol, and 15 cc. of alcoholic solution of lithium chloride* and the flask placed in hot water to prevent the salt depositing.

The cold silver solution is now to be added, in the dark room, to the collodion, and well shaken; some will separate out, but this is of no moment. Then the hot bromide solution is added in about fifteen portions to the silvered collodion, and the whole well shaken after each addition; the bromide flask should be rinsed out with alcohol and water, and this added to the collodion. The emulsion must now be vigorously shaken for about three minutes, and then allowed to stand for two or four hours. This does not increase the speed, but the collodion becomes thinner and is easier to use. In order to test the emulsion, a drop or two should be placed on a sheet of glass, a little alcohol and ether added, and rubbed with the finger; and it should, when examined by white light, appear red and not grey, which shows that it is coarse-grained and that the bromide solution has been added in too large quantities at a time. It is advisable to test the emulsion to see that there is excess of chloride, and for this purpose 4 to 5 cc. of emulsion should be placed in a test tube, and 10 drops of nitric acid and 10 cc. of water added, and the whole well shaken and filtered into another test tube and a few drops of silver nitrate solution added. There should be a copious cloudy white precipitate. The emulsion is, after standing the stated time, to be precipitated with water by adding in small portions 300 cc. of water, shaking well after each addition, and then the mixture should be poured into a

flask containing about 3,000 cc. of ordinary water. After shaking or stirring, the separated emulsion should be allowed to settle and the water decanted off, and this operation repeated five or six times, and then the emulsion collected on a linen filter and freed by squeezing from as much water as possible, and then damped with alcohol and pressed again and again. The sandy yellow emulsion must not be allowed to dry, but whilst still damp dissolved in from 350 to 450 cc. of alcohol and 400 to 550 cc. of ether, and then when dissolved filtered by pressure through wash-leather previously washed with alcohol and ether. The quantity of alcohol and ether used to dissolve the emulsion has considerable influence on the character of the emulsion, for the brilliancy and vigour of the negative increases with the concentration and richness in silver. The freshly dissolved emulsion frequently works at first somewhat foggy, but after a few days gives absolutely clean negatives. It is about twice the sensitiveness of a wet collodion plate, and has a gradation totally different, agreeing more nearly with that of the platinotype paper.

Increased contrast can be obtained with the emulsion by the addition of a chromate and 5 cc. of a 1 per cent. aqueous ammonium bichromate solution should be added to 15 cc. of alcohol, and of this mixture from 0.5 to 3 cc. be added to every 1,000 cc. of emulsion. But this must be done with care, for the addition of 1.5 cc. reduces the sensitiveness to one-half, and that of 3 cc. reduces the speed to one-sixth. An addition of eosine acts in the same way without reducing the speed, however.

THE MICRO-PLANAR LENS.

AFTER Mr. Pigg's paper appeared in this journal on October 30th, 1903, I sent you a letter which you printed the following week. I stated in that letter seven points on which Mr. Pigg's paper was defective, and as to which further information was required. Two only of these may be mentioned now. The first was the photomicrographs produced by him with his two lenses were not of the same size to enable a fair comparison to be made; and the second was he did not specify the exact focal length of the microscope objective he used, nor did he name the maker. This has been followed by a paper by Mr. Walmsley in the JOURNAL of the 8th inst., which is illustrated by some photomicrographs, which are of the same size, thus obviating the first of the above objections stated by me; but as to the second objection we are no "forrarder," but rather the reverse. As to the second objection, he says he used a 75 mm. micro-planar by Zeiss equal to 3 ins. focus; and as to the micro-objective he used a 3 in. objective by Beck, which he says he is the happy possessor of. "I do not believe," he says, "a finer 3 in. exists, although it was made more than twenty-five years ago. It is converted for photomicrography," he says, "by Wenham's method, the insertion of a double convex lens of some 6 in. focus in the extreme rear of the mounting." He proceeds to give some other details about the two lenses he used, the Zeiss and the Beck, which do not concern us here. What does concern us is that he specifically states under Fig. 5, "Photomicrographed with Beck's No. 3 in. Microscope Objective." Now, it may be at once admitted that at the time Mr. Wenham suggested the insertion behind the micro-objective of a non-achromatic lens to correct it for the chemical focus, micro-objectives at that time could be had which could be used without such adventitious aid. It is, however, no longer the case now. To the placing of this single lens behind the micro-objective there are two objections. The first is that it destroys to a considerable extent, even in a low power, the fine corrections which the maker gives the objective. A very special illustration of this may be cited, viz., that of the great Lick

* To make this 10 g. lithium chloride should be dissolved in 10 cc. of water, and 90 cc. of alcohol added, and the solution filtered.

telescope with an object glass of 36 in. diameter. It was found necessary to make a lens of 30 in. diameter to place in front of the objective to convert it for the chemical focus. This lens had the effect of shortening the focus by 6 ft., and at the same time caused such bad definition that when photographing the moon they have to shut down the aperture to 8 in. The second and most serious thing, however, about the addition of this 6 in. focus lens, and one which Mr. Walmsley seems in utter ignorance of, is the fact that he has by this additional lens converted his Beck 3 in. objective into a 2 in. one, and on his photomicrographs, therefore, no reliance can be placed on making any comparison with a micro-planar of 3 in. focus. Mr. Walmsley does not even know the focal length of his added lens; he only says it is of some 6 in. focus. Mr. Walmsley is believed to be one who has written a good deal about photomicrography for some years past. He has quite recently published a book which he calls the "ABC of Photomicrography," and yet it is perfectly plain from the above that he has, as regards the above lens, at any rate, the ABC of that art science yet to learn.

I have not got a Beck 3 in. objective, although I have occasionally seen them; but I have had very many 3 in. and 2 in. objectives by Wray through my hands. I have at present in my own cabinet both a 3 in. and a 2 in. by that maker. To make the above statement as to effect of adding a 6 in. focus to a 3 in. yet more clear, I measured the magnifying power of my 3 in. Wray in the microscope itself, and, as probably your readers may not know how this is done, I shall describe it here. My Wray 3 in. is made for the long 10 in. tube—that is, 10 in. from the shoulder of the objective to the level of the eye-lens of the eyepiece. Placing, then, on the stage of the microscope a Zeiss micrometer divided into mm. the object glass, the 3 in., was screwed into the tube, and then a Leitz eyepiece micrometer, also divided into mm., was placed in the upper end of the tube, first of all removing the field lens of that eyepiece. In this way the magnified image of one mm. on the stage micrometer was projected on to the eyepiece micrometer without the reducing action of the field lens, and it was found that one mm. on the stage covered 3.5 mm. of that in the eyepiece—that is to say, the divisions of the two micrometers being equal, the magnification required only to be read off without any calculation, and the object-glass thus by itself alone magnified $3\frac{1}{2}$ times. I had previously prepared a 6 in. focus biconvex lens, just the same thing it is supposed Mr. Walmsley uses, and dropped it into the micro-tube resting on the object-glass. Again the magnification was read off, and it was found to be 5.25; or with this additional lens the 3 in. object-glass became at once a 2 in. one. These facts are beyond dispute.

As the whole of Mr. Walmsley's paper proceeds on the assumption that he was using a true 3 in. objective in opposition to a 3 in. micro-planar, while all the time, although he did not know it, he was using a 2 in. objective the whole of his paper, and the deductions he draws from it, and his illustrations, fall to the ground, and the paper must be held to be *pro non scripto*, as it proceeds upon an essential error.

I have no wish to criticise either the photomicrographs of Mr. Pigg or Mr. Walmsley in detail. The information they have given does not enable that to be done.

Neither my Wray 3 in. nor the 2 in. require any lens placed behind them to get the chemical focus. They both give good, crisp negatives without such addition; and they are not alone in this respect. Many of the modern objectives by reputable makers work in the same way without adventitious aid.

Notwithstanding the papers of Messrs. Pigg and Walmsley, I feel sure the micro-planars stand on too high a platform to be affected by what they have done.

If I should say that no better lenses exist than my 3 in. and 2 in. Wrays I should state what is neither true nor honest, as I have seen and handled many quite as good, perhaps better. Besides, it would be bragging, and that is a thing which we do not practice ourselves, nor like to see it in others, in this grey, grey town in the far, far north. W. F.

FIFTY YEARS AGO.

[From the *Liverpool Photographic Journal*, now *THE BRITISH JOURNAL OF PHOTOGRAPHY*, January, 1854.]

RESUME OF THE OPERATIONS OF THE LIVERPOOL PHOTOGRAPHIC SOCIETY FROM THE COMMENCEMENT.

This Society was founded on Tuesday, March 22nd, 1853, at a meeting called together by advertisement, and at which Mr. J. A. Picton was called to the chair. Mr. Samuel Holme, then Mayor of Liverpool, was elected President; and the vice-presidents, treasurer, joint secretaries, and Council, were appointed.

The third meeting of the Society took place on May 3rd, at which, after the election of members, Mr. Mackinlay exhibited a folding camera and box, suitable for taking views in open country, and read a paper describing it.

Mr. Knott read a paper, "Practical Notes on Glass Positives." Dr. Edwards and Mr. W. Barker exhibited some microscopical collodion specimens, and gave explanatory remarks on the mode of taking microscopical objects, and the adaptation of the camera to that purpose, the arrangement of which was also shown.

The fourth sessional meeting was held on June 2nd, when Mr. Frank Howard read a paper upon "Photography in Connexion with the Fine Arts," which led to an animated discussion on the part of the practical members, Mr. Firth and Mr. Burgess, Mr. Newlands and Mr. Corey. Mr. C. Bell exhibited and described "A Plan for Taking Stereoscopic Views in the Open Country." Mr. Chadburn exhibited some beautiful photographic views in Venice.

At the fifth meeting, on July 5th, Mr. Forrest exhibited a camera slide frame, the inside of which was made of glass, with the view to prevent the sensitive plate being affected by the absorption of the chemicals into the wood.

Mr. T. A. Humphries exhibited one of Mr. Mayall's Crayon Photographs, and the Chairman mentioned a suggestion by Mr. Frank Howard, that the art of photography should be applied in assistance of the sciences of physiognomy and ethnology, by taking photographs of individuals of the various foreigners who visited this port; and Mr. Mackinlay exhibited some specimens of photographic printing without nitrate of silver, by which ladies may be enabled to produce copies of lace, crochet work, etc., in the most pleasing shades and colours, without danger of staining their fingers. He then described the modes of operation, and the chemicals used for the production of the various tints.

The sixth sessional meeting was held on August 2nd. Mr. Wood, of the establishment of Abraham and Co., of Liverpool, exhibited a very complete "Portable apparatus for taking views in open country."

Mr. Burgess exhibited an American camera, with Knight's and other improvements, and described some modifications he had personally found useful. Mr. Frank Howard read a paper on the "Artistic Distribution of Light and Shade."

At the seventh meeting, September 2nd, Mr. Foard read a paper, "Notes on the Daguerreotype," followed by a discussion on the relative merits of the daguerreotype and collodion process. After which Mr. J. A. P. McBride read a paper on "Photography in Connexion with the Fine Arts," on which some discussion also took place.

On October 4th the eighth meeting was held. Mr. G. R.

erry read "A Digest of Mr. Fox Talbot's Patents." Mr. Kinson exhibited a stereoscope camera. Mr. J. A. Forrest exhibited and described a folding camera for taking views in open air by the collodion process, in a very portable form; and Mr. Keith exhibited specimens of positives taken on coloured glass by the collodion process.

Mr. Burgess exhibited a camera, sent by Mr. Wilkinson, intended at Paris, to carry two lenses, so as to take the two views of the stereoscope at one time and on the same plate. It was called a quintoscope.

On October 24th the Society was invited to inspect the photographic reports of the progress of the Crystal Palace, now erecting in Sydenham. Mr. T. C. Archer, the agent for the Crystal Palace Company, had kindly consented to exhibit these photographs, taken by Mr. Delamotte, amounting in number to nearly fifty, at the rooms of the Photographic Society in Lord Street. On this occasion Mr. Atkinson exhibited some large photographs of Egyptian architecture, and negatives taken on albumenised paper.

The ninth sessional meeting was held on November 1st, and was principally devoted to the consideration of the paper processes in photography.

Mr. John Morecroft exhibited a great number of negatives, taken with nearly uniform success by Buckle's process, and positives printed from them for the stereoscope as arranged by Professor Wheatstone. From these negatives a selection has been made, of which Mr. G. R. Berry has kindly offered to print positives, of which each member of this Society will be entitled to two. They are eight inches by seven, and of the most exquisite beauty—combining sharpness with aerial perspective to an extent very rarely seen.

Mr. Keith exhibited the calotype process, in which he had been very successful.

Mr. G. R. Berry then described a course of proceeding with paper, which he had just discovered, of much more simple character than any hitherto described, which was perfectly effective, both for taking photographs by the camera and for printing; and the latter might be done by gaslight even better than by daylight.—[It will be seen by the report of the January meeting which appears at full length in this Journal, that Mr. G. R. Berry has modified his formulæ in a very slight degree. This process will be printed the positives from Mr. John Morecroft's negatives, for presentation to the members.]

At this meeting Dr. Edwards exhibited some beautiful photographs, taken on collodion, of a rare species of electric torpedo, *Torpedo nobiliana*, recently caught at the mouth of the Dee. They were positive and negative, and of back and front of the fish.

Mr. Mackinlay exhibited some specimens of views taken by the collodion process, in which he had secured the greatest density in the blacks, in combination with the full development of the half-tones, by the use of vegetable naphtha. He also described some advantages he had obtained in printing by wash of sea-water over the paper to commence with. Another wash, composed of tartrate of antimony, salt, or sal ammoniac and water, he had found remarkably good.

He had also discovered that a weak negative, by printing through blue glass, would produce very effective positives.

He had also observed that pictures taken very rapidly by the camera required to be subjected a long time in the developing solution; but that a much shorter time was required developing when the action of the camera was slower.

Mr. J. A. Forrest mentioned that Mr. McInnes had devoted a great deal of time to perfecting a portable apparatus for taking collodion negatives, and had also discovered a means of removing the collodion film—upon which a photograph had been taken—from the glass, so as to obviate the necessity

of carrying so many plates of glass—of which the weight and liability to breakage formed the principal objection or difficulty in making the collodion process convenient for carrying about.

Mr. Firth said that he had been successful in taking photographs on collodion floated on waxed paper, which would obviate the necessity of carrying more than one plate of glass, or the removal of the film from the glass, which he thought would be very hazardous to the photograph.

Mr. Burgess said he had taken photographs on collodion floated on gutta serena, which he had no doubt would supersede either paper or glass.

The tenth meeting took place on December 6th, when the Chairman congratulated the Society upon the great accession to their numbers—their register showing one hundred and thirty-five members. The next session would commence on March 18th, when he had no doubt the Society would be still more increased, as each member enrolled in the interim would be entitled to the prints from Mr. John Morecroft's photographs.

Mr. Mackinlay exhibited a large folding camera, constructed for the paper process, in which considerable improvements had been effected upon the first that he had exhibited on May 3rd.

A discussion then followed upon the relative advantages of the collodion and paper processes, in which Mr. Forrest, Mr. Burgess, Mr. Mackinlay, and Mr. Chadburn took part.

Mr. Frank Howard mentioned the difficulty which existed in procuring suitable paper for any of the paper processes, except that of Mr. Berry, and expressed his opinion that the photographers in general were disposed to look too much for sharpness; and he exhibited a drawing to show the defects of too much hardness or distinctness in the individual objects.

On December 15th the members were invited to inspect some very large photographs, taken on albumenised paper by Mr. Sanford, which were brought down from London, and exhibited by Dr. Edwards, who, on behalf of Mr. Sanford, presented a set of prints from them to the Society.

On Friday, February 26th, Lord Kelvin presents the certificates and prizes at the annual prize distribution and conversazione of members and students, at the Northampton Institute, St. John Street Road, London, E.C.

THE HON. Secretary of the Longton and District Photographic Society writes: "My attention has just been drawn to a printer's error in our exhibition prospectus and entry form. It there states that entries close on Tuesday, January 25th, whereas it should read Tuesday, January 26th. For the information of intending exhibitors, may I ask your kind notice and correction."

"PICTURE Titles for Painters and Photographers, Chosen from the Literature of Great Britain and America," is the title of a forthcoming book by Mr. Alfred Lys Baldry. The prospectus states that it will be found of the very greatest value to painters, sculptors, photographers, and others. The many quotations it contains not only supply titles for pictures already completed, but suggest subjects for future work. The book is so arranged that suitable titles can be found with the greatest possible ease in the shortest possible time.

MR. GEORGE HARRIS, a gentleman describing himself as an artist, and living in Trefoil Road, Wandsworth Common, was summoned, on Wednesday last week, at Wimbledon Petty Sessions, by the Conservators of Wimbledon Common, for cutting down three large pieces of holly. George Cox, a keeper, said that he found the defendant in the woods on Sunday morning, January 3rd, with the holly lying in front of him. The defendant told him that he was sorry if he had done wrong. The defendant pleaded that he had cut down the holly to get a better view, as he wanted to obtain some snap-shots. He was fined 40s.

THE FUNCTIONS OF TRICOLOUR FILTERS.

The diagrams and illustrations which appear on this and the previous pages were omitted from Messrs. Bull and Jolley's paper published in last week's JOURNAL.

It is well known that the German Empress excels in the photographer's art. She it was who furnished the illustrations for the narrative of the tour of the Emperor William II. in Palestine, published by Baron von Mirbach. Her Majesty has taken advantage of the Christmas holidays to instruct her two youngest sons in the art of photographing in colours, and her pupils have made surprising progress.—"New York Herald."

THE Committee of the Professional Photographers' Association have taken the first step towards the establishment of that much-required institution—an examining board for professional photographic assistants. The sub-committee which has the matter in hand held its first meeting last week, but with the most assiduous attention to business, it can hardly be hoped that a workable scheme will be evolved for many months at least. The problem to be solved is undoubtedly a very difficult one, and although almost every professional photographer in the kingdom is personally interested in the success of the undertaking, experience of the attitude of professionals towards other attempts to benefit their order hardly lead us to expect that the Association will receive much assistance from outside its ranks. Still, the harder the battle the greater the glory, and we heartily wish the Association a successful achievement of its purpose.

New Apparatus, &c.

The Ideal Portrait Lamp. Geo. Houghton and Son, Ltd., 88 and 89, High Holborn, W.C.

The apparatus consists of a frame, constructed of aluminium rods, supported by a standard, adjustable for height, with an arrangement for clamping to a stool or chair. When erected, over the frame is placed a cover of fireproofed cloth, the front consisting of one thickness of cambric, the back and sides having, in addition to the cambric, an outer thickness of dark coloured calico. The lower portion of this cover hangs loosely. The lamp consists of a shallow tray in which a special flash powder is placed. Connected with the tray is an arrangement for detonating a percussion cap to ignite the powder, the trigger being released by a pneumatic ball and tube, another tube from the same ball being connected with the shutter of the camera, and adjusted so as to open the shutter just in advance of the release of trigger. The composition is an extremely rapid-burning one, and the flash so instantaneous that the sitter can be taken in the act of talking, without the slightest trace of movement showing. When the exposure has been made the loose drapery is gathered up, imprisoning the smoke, and the cover is lifted off the standard and removed to the open air or placed outside a window for the smoke to disperse.

We had an opportunity of seeing the apparatus at work at night in an ordinary photographic studio under conditions which put its utility to the fullest test. The negatives, which were made in our presence, were equal to those taken by the best electric light systems, and the ordinary faults of flashlight portraits were absent, owing no doubt to the diffusion of the light by means of the cambric screen. The apparatus proved perfectly efficacious in preventing the escape of smoke into the room, and as it is so independent of any outside accessories, so portable and so easily set up and adjusted in any position, it will doubtless be highly appreciated by those photographers who are often called upon to take at home portraits. Indeed, when used for this particular purpose it is probable that better results would always be obtained than by daylight, and the advantage exists that the position of the subject may be chosen to suit the furniture and decorations of the room instead of being limited by the position of the windows. The quantity of powder used is small, about 40 grains sufficing for a head and bust portrait, and we are informed that it is not of a dangerous nature and not liable to explosion by detonation or friction.

Messrs. Gardner and Co., of West Nile Street, Glasgow, are the Scottish agents for the lamp.

Marion's Supreme Plate. Manufactured and sold by Marion and Co., Ltd., 22-3, Soho Square, London.

Messrs. Marion and Co. have added to their series of dry plates a new one, which, from its character, should meet with much success.

The new plate does not make pretensions to orthochromatism, but claims supremacy of quality, supremacy of speed, and supremacy in ease of working. These desirable characteristics appear to have been secured by means of an emulsion of extreme sensitiveness, rich in silver, coated thickly upon excellent glass, and with great care to ensure freedom from technical defects. It will be remembered that Messrs. Marion and Co. were the pioneers who introduced the new plates of extreme rapidity. Their P.S. plate won immediate recognition for its speed. The Supreme is of similar rapidity, and bears the No. 250 H. and D. The conscientiousness with which the firm has used the Hürter and Driffeld system for the measurement of the speed of plates is unquestioned, and the figures we have quoted may be taken as a true index of the possibilities open to the photographer who uses these plates. Thus we find that the amateur using one of the cheap hand cameras, with a lens of the low intensity of F/11 may, even at this season of the year at noon, obtain a fully exposed negative with these plates in 1-15 to 1-25 second when photographing, on a very fine day, a close object, or landscape with heavy foreground. The exposure for an ordinary landscape would not exceed 1-50 second, under similar conditions, but at the brightest season of the year the stop might be reduced to F/20 for such a subject. If the photographer is content to rely upon development for obtaining greater detail, a further reduction of the exposure may be made. We have tested a sample of these plates, and directed our attention more especially to their quality and their latitude of exposure. The test for latitude was a severe one. Two plates were exposed upon a subject presenting great contrast. To the one an exposure of 12 seconds was given, and to the other 144 seconds. Both plates were developed simultaneously with the same developer for the same length of time. The exposure of 12 seconds was correct, as it gave some detail in the deep shadows. But the second negative, although exposed twelve times as long, still gave a useful result. The grain of the deposit is very fine, considering the rapidity of the plate, and the films are of great perfection. A plate with this latitude of exposure should present the minimum of difficulty to the inexperienced photographer, whose greatest errors usually occur in exposure. We also gave particular attention to the gradation of the image, and think the series will give much satisfaction to those who require a plate with a long scale of gradation, rendering subtle differences of half-tone. Such plates are very valuable for delicate effects of light and shade.

New Developers for Gaslight Papers. Sold by John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, W.C.

The metal-hydrokinone developer which Messrs. Griffin and Sons have sold for a long time in various forms of preparation under the title of M.Q., is now placed upon the market in a new form which is certainly calculated to add to its already extensive popularity on account of the convenience which accompanies its employment. The developer is compounded in a highly concentrated single solution which keeps without deterioration and which requires only simple dilution with water to form the developing solution. The concentrated developer is sent out in a stoppered bottle with a rather wide mouth, and the glass stopper is moulded so that it constitutes a cup which acts as a measure. The arrangement is especially designed for use in the development of Velox paper, but there is not the slightest reason that the same should not be applicable to the development of any other sensitive surface for which metal hydrokinone is suitable, the dilution being modified according to purpose. The method of putting up is certainly a most convenient one.

An entirely novel developer for Velox and other gaslight papers is now sold by Messrs. Griffin under the name of Sepol. As its name suggests its peculiarity is that it produces an image of sepia tint instead of the usual black or blue black. Following the instructions given, that is to say, giving the sensitive paper an exposure of four to six times that normally required, and compounding the developer as instructed we found it quite easy to produce prints of a pleasant brown tint, and not difficult to obtain a reasonable amount of uniformity of tint even when employing negatives differing in character. We should imagine that this developer will prove a very popular introduction as it entirely obviates the necessity of any troublesome and uncertain process of toning the developed and fixed print. Sepol may be had packed in cartridges or in concentrated solution.

ties in Enlarging Apparatus. Manufactured by John J. Griffin and Sons, Ltd., 20-26, Sardinia Street, London, W.C.

Series A fixed focus enlarger constitutes an enlarging apparatus reduced to the elementary and necessary principles, nevertheless its limitations it is quite efficient, and, moreover, is convenient in construction is ingenious, and it folds to a convenient size. The apparatus is for enlarging from $\frac{1}{4}$ plate negatives to plate size. The front part consists of a box, one end having

to carry the negative to be enlarged from, and the other end carrying the lens, which is an achromatic combination, fitted with a shutter for exposing. Bellows of red and black cloth connect the front part with the back, which includes an arrangement for holding the bromide paper upon which the enlargement is to be made. The paper is merely placed face upwards in the back, and covered with a sheet of glass. The bellows body is held rigid by struts on each side. The apparatus is adjusted exactly to enlarge from $\frac{1}{4}$ to 1-1 plate, and no focussing arrangement is necessary, the distances being adjusted in manufacture. For exposure the aperture is taken bodily into the open air and placed, negative upwards, under the sky. As the price is within the most limited means, as makers say, the enlarger is an excellent one for the tyro, or for the amateur who wishes to try his hand before going to much expense.

The Series C folding enlarger is a piece of apparatus on a much more elaborate scale; indeed, it possesses the means of every adjustment that could possibly be required. The general appearance of the apparatus will be realised from the illustration. It is made of brass, enlargements up to 10 in. by 8 in. The woodwork is polished and the bellows are cloth, and the metal-work is lacquered brass. The lens is an achromatic combination, fitted with stops and an iris shutter. The dark slide is of the usual construction, of a metal back, and is fitted with carriers for 1-1 and $\frac{1}{4}$ plate. The negative is taken to the negative to be enlarged from is fitted to the carrier so that it may be shifted from side to side, and thus a portion of the negative only may be used to enlarge from, and it may be adjusted obliquely, so as to rectify any want of uprightness in the negative. A rack and pinion is provided for focussing in the ordinary way, but the difficulties in focussing and adjusting the relative positions of screen, lens, and negative are simplified enormously in using

the apparatus by a device with which it is fitted, which has the effect of automatically adjusting the relative positions of the negative and back in accordance with the conjugate foci of the lens for the ratio of enlargement. For daylight exposures the makers direct the apparatus should be taken outdoors and pointed upwards, so that the illumination is obtained directly by skylight. There is, however, no reason why the apparatus should not be kept horizontal and the illumination obtained from a white reflector. A special plate carrier is supplied with the apparatus to carry lantern size plate,

and lantern slides may be made by reduction from negatives of any size from 10 in. by 8 in. downwards.

Griffin's gaslight attachment provides a means of employing artificial light with either of the before-mentioned apparatus for enlarging. It consists of a curved metal-plate, whitened to form a reflecting surface, having its sides continued in deeper curves almost to form cylinders. The interior of the cylindrical ends are of bright metal to form reflectors, and each contains an incandescent burner as the sources of illumination. Fittings are provided for attachment to ordinary gas supply by means of an indiarubber tube. The arrangement is also specially applicable for use in making lantern slides by reduction. The outside of the metal-work is japanned black, and the price at which it is offered is extremely reasonable. Although primarily intended for use with the enlarging apparatus we have described, it is equally applicable to most other apparatus constructed on similar lines, and for lantern-slide making any simple means improvised for the purpose of holding the negative in front of the reflector in conjunction with an ordinary camera would constitute a perfectly effective installation.

The "Alphengo" Reflecting Enlarging Lantern. Manufactured by W. C. Hughes, Brewster House, 82, Mortimer Road, London, N.

The apparatus consists of a metal chamber, the interior lighted by two lamps, which may be for oil, incandescent gas, electric light, or acetylene. At the back is a white screen or reflector, and at the front an arrangement for holding the negative to be enlarged. In front of the negative holder is a platform upon which can be placed one's ordinary landscape camera, and the whole then constitutes a

Fig. 1.

FIG. 2.

complete enlarging system. The illustrations, figs. 1 and 2, show a front view of the apparatus with and without the camera in position for making an enlargement. Enlarging, however, is not the only use to which the apparatus may be put. It is equally available for making lantern slides by reduction, or for copying prints by artificial illumination. For the former purpose the ordinary camera is used, but, of course, in its natural way, with the front of the lens toward the negative, the ordinary dark slide holding the lantern plate by means of a carrier. For copying, the print to be copied is adjusted in front of the back or reflector, and the lens of the camera pointed towards it through the front aperture, the negative carrier being

FIG. 3.

removed. Fig. 3 represents a bellows body attachment for fitting to the front when the apparatus is in use as an enlarger, instead of a camera when a camera is not available; it is not supplied as part of the apparatus, but the reasonable price at which it is offered and its convenience for carrying a large lens, will no doubt tempt many to include it in their purchases. For all the purposes we have enumerated the apparatus is undoubtedly efficient, and the use of reflected light for illumination in making enlargements or reductions from negatives instead of a condenser is recognised as being the

preferable system, when the quality of the results is important. We are very much surprised that an arrangement of the kind is not universally in use amongst professional photographers for copying prints by artificial light, especially in the dark days of winter.

"Porcelain" S.C.P. Slow Contact Paper. Manufactured by Wellington and Ward, Elstree, Herts.

Apart from the convenience of being able to dispense with dark room illumination for manipulatory purposes, development papers of the S.C.P. type are found to be superior to ordinary bromide papers for making contact prints, especially of a small size, in the better rendering of the shadow detail and the less liability to harsh results in the endeavours to secure sufficient depth in the lower tones. The new grade of S.C.P. termed "Porcelain," which Messrs. Wellington and Ward are placing on the market does not differ, we believe, as far as the sensitive material of the paper is concerned from the S.C.P. paper already in use; the improvement is in the surface of paper which is fairly described by the title given it. The paper is of very pure whiteness, and the character of the emulsion enables prints to be made on it with ease from reasonable good negatives having a peculiar richness in the deep shadows. The specimen prints which accompanied the sample of the paper sent us were of an attractive blue black tint and perfect in gradation. Choosing the amidol developer mixed according to the formula given in the instructions as an alternative to metol-hydrokinone we found not the slightest difficulty in making equally satisfactory prints from our own negatives.

Messrs. Wellington and Ward have also introduced a new grade of bromide paper marked "Xtra R." This is a paper very similar to Whatman rough drawing paper in character, and naturally more suitable for large sizes and broad effects than for the rendering of detail. As the emulsion with which it is coated is that usually employed for the Wellington and Ward bromide papers it is needless to say that the results obtainable on the new grade of paper when the subject is suitable leave nothing to be desired in quality, and it is not an unimportant feature of the paper that the price is the same as the ordinary grades.

Patent News.

The following applications for patents were made between January 1 and January 9, 1904:—

Shutters.—No. 30. "Improvements in or connected with photographic shutters." The Thornton-Pickard Manufacturing Company, Ltd., George Arthur Pickard and Ernest Vary Piercy.

Carbon Printing.—No. 47. "Improvements in the photographic process of pigment or carbon printing." Charles Sawyer.

Cameras.—No. 119. "Improvements in photographic cameras." (Date applied for under Patents Act, 1901, March 25, 1903, being date of application in United States.) Complete specification. Henry William Hales.

Shutters.—No. 267. "Improvements in or relating to shutters for photographic purposes." Arthur Lewis Adams.

Lighting Apparatus.—No. 284. "An improved lighting apparatus for photography." Complete specification. Joseph Leclerc.

Printing Frame.—No. 309. "Improvements in photographic printing frames." William Frederic Butcher.

Printing Frame.—No. 346. "Improved photographic printing frame." Card Edward Hoditz.

Cameras.—No. 426. "Improvements in photographic cameras." Arthur Lewis Adams.

Cameras.—No. 619. "Improvements in and relating to cameras." Henry James Spratt and George Albert Spratt.

Apparatus.—No. 627. "Improvements relating to photographic apparatus." (August Blanc, Switzerland.) Henry Harris Lake.

PHOTOGRAPHIC Convention of the United Kingdom.—There will be a meeting of the Council at Anderton's Hotel, Fleet Street, E.C., on Thursday, January 28th, at six o'clock, to receive a report from the local committee and to discuss the proposed arrangements for the meeting to be held in Derby in July next.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.

28.....	Liverpool Amateur Photo. Assoc.	

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 14th.—Mr. T. K. Grant in the chair. Mr. A. Bedding exhibited two photographs of skeletons in what were evidently carefully built vaults. The photographs were made within the precincts of Old Bermondsey Abbey, and Mr. Bedding, having tried in vain to get any history of the Abbey, asked if anyone present could tell him where such information could be obtained.

Mr. Anthony exhibited a book of views printed in two colours (pink and blue), slightly out of register, together with an arrangement for viewing the same—viz., a spectacle containing a red and a green glass, which gave the appearance of relief. The idea, of course, is not new, but is interesting.

Mr. Haddon detailed a series of experiments he had made with the object of finding exactly the action of barium chloride when used as an eliminator of hypo, and said that barium thiosulphate, when formed, and decomposed sulphur would be formed in the process, rendering any chance of permanency nil.

CAMERA CLUB.

A "LADIES' night" at the Camera Club is usually regarded as a "dies non," so far as lecturing is concerned, and a programme of much lighter kind is generally provided upon these happy occasions. But this practice has been departed from lately, and Mr. W. Godfrey, the hon. secretary and prince of organisers, has succeeded in securing the co-operation of some lady lecturer. On the 11th inst. the choice fell upon Mrs. Watts-Hughes, who gave an interesting account and demonstration of her method of producing what she terms "voice figures."

Students of natural philosophy know well enough that sound waves have often been made to produce on suitable media geometrical patterns of very beautiful, and sometimes very complex, form. If we remember rightly, the first experiments of this kind were due to Christiaan Huyghens, the German philosopher, who showed a century ago that if a series of metal plates will arrange itself in definite positions, the nodal lines when the plates are vibrated by the application of a violin bow. There was a much later instrument by Professor Sedley Taylor, called the phoneidoscope, which consisted of a glass cup supported on a stand, with an attached tube which could be applied to the mouth. A soap film was drawn across the horizontal mouth of the cup, and when a note was sung into the tube the film was thrown into the most beautiful ripples, which, when seen by reflected light, were gorgeous both in form and colour.

Mrs. Watts-Hughes has made an instrument of almost identical pattern, but instead of using a soap film she stretches over the mouth of the cup a piece of indiarubber tissue, placing upon it a vibratile surface sand, lycopodium, or other dusty materials.

sings into the attached mouthpiece. As might be expected, she produces by this action various geometrical forms, just as Chladni a hundred years ago, but it is obvious that the instrument is much rougher than the delicate soap-film apparatus devised by Sedley Boscawen, and the effects are of a rougher description. Mrs. Hughes seemed to hold out the hope that a study of these figures and their production would be useful to singers, but we confess that we do not see how that can be the case. If she could affirm that Patti, Mrs. Reeves, Edward Lloyd, or some other of our leading vocalists had learned to sing that way, we might be inclined to agree with her, but to our notion singing into a tube, whatever pretty figures it may cause, could not possibly aid in good vocalisation.

Mrs. Hughes calls the instrument in its new form the eidophone, and as an introduction to its consideration she spoke of the general nature of musical vibrations, and pointed out how the number of impulses per second were doubled with the rise of each octave. She showed how individual ears differed in their ability to appreciate high sounds, and by a process of reasoning that was not too far-fetched connected the highest number of sound-vibrations with the vibrations of the ether which gives us light, and identified them with the heavens above, and the low sounds with the earth beneath. As she frankly admitted there were many present whose knowledge of light-undulations was greater than she could boast of, she did thenceforward content herself by dealing with sound.

A very large number of photographs of the "voice figures" formed by the vibrating disc of the eidophone were thrown upon the lantern screen, and many of them were of a very curious description, but a critical observer could not help wishing that the figures themselves reflected from the disc, and shown in actual movement, could have taken the place of many of these pictures. The variety of the figures was very great indeed—so great, in fact, that the lecturer's attempt to classify them was not at all successful. It would not be the serio is student much to divide them into daisy forms, ferns, trees, and so on. And in the production of some of the figures there was a little too much of the personal equation to make them any scientific value. Thus, in some of the most curious trumpet-like forms, which showed a most surprising stereoscopic effect on the screen, the method of procedure was this: A tube with an india-rubber disc at its end was drawn by hand over a sheet of glass which had been covered with liquid water-colour, while a note was steadily sung into the tube. The consequence was that the liquid film was thrown into ridges, and there is no kind of doubt in seeing that with one note an octave higher than a previous one those ridges must be half the distance apart.

We presume that the lantern slides shown were the actual plates on which these sound vibrations were originally recorded, and must admit that some of them had a weird fascination about them. But they do not give any definite information, as does the effect of a vibrating tuning-fork upon a smoked surface. They certainly suggest forms and groupings for the use of decorators, as the kaleidoscope will; but they do not appear to be of any scientific importance. A short musical programme followed the lecture, and everyone went home about 11 p.m.

On the following Wednesday there was a house dinner at the club to afford an opportunity of presenting to Mr. Wallace Godfrey a handsome silver tea service on his marriage. We will close this account of the proceedings by wishing him and his bride both health and happiness.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION: EDINBURGH BRANCH.

JANUARY 8TH.—Present, Messrs. Yerbury, Bibbs, Heaven, Patrick, and Moffat. Mr. Yerbury occupied the chair. Letters of sympathy were received from Messrs. Crooke, Balmain, and Crawford. A paper was read from the family of the late Mr. Alexander Inglis, in which one sent by the hon. secretary, at the request of the association, condoling with them in their recent bereavement.

The following subjects were discussed:—

How do picture post-cards affect portrait photographs. All the members present took part in this discussion. It was unanimously decided that it was very undesirable to print picture post-cards in this way, as it would tend to hurt the ordinary portrait business.

The recovery of silver.

Mr. Balmain wrote that he had, for some time past, been trying to recover the silver from the old hypo baths, both negative and print fixing. He had come to the conclusion that the results were not worth the time and trouble expended upon them. The members present agreed with the above, but the majority were strongly in favour of saving the cuttings of the silver printing paper, and also precipitating the silver from the first washings of the prints before toning and fixing. Copies of the "Rottenotint portrait," reprinted from "Judy," were distributed. A vote of thanks to the chairman terminated the proceedings.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE following are extracts from the annual report:—The membership roll at the beginning of the year contained 326 names; the number of new members elected during the year amounted to 28, resignations, lapses, and deaths to 26, leaving 328 names in the books at the end of the year. The coffee meeting held on Wednesday afternoon, from 4 to 6 o'clock, continues to be well supported, and the lantern being available at these meetings, affords members an opportunity of judging the quality of their slides, besides proving an attraction to the meeting. The Thursday evening lectures and demonstrations have also been well attended, and your council cordially invite suggestions from members, with a view to rendering the meetings still more interesting.

The thanks of the society are due, and are hereby tendered to the ladies and gentlemen who have given lectures and demonstrations before the members or have otherwise given their services for the benefit of the society, to the judges in the annual competition, to Dr. J. W. Ellis, F.E.S., for book, "The Mediæval Fonts of the Hundred of West Derby and Wirral"; to Mr. F. K. Glazebrook, for book, "Cantor Lectures on Glass for Optical Instruments"; to Mr. E. Rimbault Dibdin for book, "Photographic Lenses" (a simple treatise); to Mrs. Paul Lange for two complete sets of lantern slides, illustrating the late Mr. Paul Lange's lectures, entitled "Southern Norway" and "Norway Revisited"; also for 27 books on photographic and other matters; to Mr. O. R. Green for 24 x 18 camera outfit with two lenses, tripod, etc.; also fourteen 24 x 18 negatives, and four framed carbon transparencies; to Mr. Fred Anyon for a bromide enlargement of the late Mr. Paul Lange; to Mr. Geo. E. Thompson, for a carbon print, entitled "Threshing Wheat"; to Mr. Edwin Kite, for an anti-mony ash tray; to the Rev. H. H. Williams, for six lantern slides of American scenery; to Mr. Henry Lupton, for three books, "Where to go for a Holiday," "The Best Cruise on the Broads and Norway Tour."

The council have to record, with deep regret, the death of two members during the year—viz., Mr. Paul Lange, elected 1885, president in 1890, 1891, and 1899; and Mr. Joseph Earp, elected 1883, and hon. treasurer from 1887 to 1890. In response to the wish of a number of members, a fund has been opened with the object of raising a permanent memorial of the late Mr. Lange, in recognition of the valuable services rendered by him to the association, of which he was so zealous a member. The memorial is to take the form of a plaque, to be offered in competition annually (or as often as the interest accruing on the invested fund will allow) to members of the association only. The sum of £62 4s. 6d. has already been promised and subscribed, and the council will be pleased to receive further contributions before finally closing the fund.

CROYDON CAMERA CLUB.

JANUARY 13TH.—The annual meeting was held on this date, and for the first time in the history of the club a contest for the post of president took place, Mr. Hector Maclean and Mr. S. H. Wratten being both nominated for the position. The contest was in every sense a friendly one, but the personal popularity of Mr. Wratten made him a dangerous opponent, as the voting showed, Mr. Maclean being appointed president for the fourteenth year in succession, by a majority of eight votes.

From the draft report it appears that the club comprises 119 effective members, including 24 who have joined during the preceding twelve months. Owing to a deficit on the exhibition and to other causes, the cash balance is not so large as was formerly the case; but in all other respects its affairs appear to be in a flourishing condition. An attractive fixture list has been gone through, and is in contemplation, and the average attendance of members has been distinctly good. Messrs.

F. W. Hicks and W. H. Rogers retire from the council, and the vacancies thus caused will be filled up at an adjourned meeting convened for the purpose, and to consider other matters which could not be dealt with during the evening. Both these gentlemen have been invaluable members of the council, and a general wish was expressed that their retirement would be but temporary. Whilst the election of president was proceeding Mr. Packham occupied the chair.

RICHMOND CAMERA CLUB.

JANUARY 14.—A discussion took place on "Films versus Plates." It was opened by Mr. Cembrano, who remarked that in the early days of films he had tried a considerable number of makes, but his experience of them was unsatisfactory, and that now he confined himself to plates. Films have the great advantage of lightness, a very important consideration, especially for those who work large sizes, and they are free from the risk of breakage to which plates are subject, but the same emulsion which, when spread upon glass, would give great rapidity, becomes much slower when spread upon a celluloid or other film, so that they are not so well suited for quick exposures as plates. Another objection that he found in them is that after exposure they must be developed within a short time. In his experience they deteriorate very rapidly after exposure, and at the end of a few months become worthless; whereas, he had kept plates for a year or more after exposure, and found that they still developed up bright and clean. Nevertheless he had seen pictures at the Camera Club, taken in India, which, to his surprise, he found had been taken upon films developed in this country months after exposure. When he goes abroad he takes plates which he brings home for development, with the certainty that they will all be good, but he could not feel the same certainty with films, and he was convinced this is one of the reasons why films are not more generally used. With films all the advantages are before, and with plates after, development. Mr. Ardaseer mentioned that he had been informed by one maker that he had tested the speed of emulsions coated upon various substances, ranging from blotting paper to glass, and he had found that the speed depends upon the degree of hardness of the supporting medium.

SOUTHAMPTON CAMERA CLUB.

JANUARY 18TH.—Lecture and demonstration on the "Ozotype" process, by Mr. Thos. Manly. Mr. Manly explained and demonstrated the simplicity and utility of his process, in an extremely lucid manner, from the method of sensitising the paper to the production of the finished print, which is of a very artistic character, and is more simple than the carbon process, inasmuch that no double transfer is required, and the undeveloped prints will keep for a longer period, which is an advantage. The method of printing is very similar to that of platinotype, and Mr. Manly claims that it has no superior in the market as regards permanency.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.

JANUARY 18TH.—First annual meeting. The report and balance-sheet was submitted and adopted, the financial position of the Society being very satisfactory. The medals and certificates awarded by the judges at the exhibition held on the 4th and 5th inst. were presented by the president, who also, on behalf of the members, presented to the hon. secretary as a token of esteem a handsome silver-mounted oak inkstand. The following gentlemen were elected officers and council for the year 1904:—President, Mr. W. T. P. Cunningham; vice president, Mr. A. J. Craston; hon. treasurer, Mr. A. Bird; hon. secretary, Mr. A. Kernon; hon. assist.-secretary, Mr. F. Slater; hon. librarian, Mr. C. S. Carr. Council: Messrs. H. C. Bird; R. Core Gardner, C.P.A.; A. F. Hawes; H. C. Hornsey; A. G. Johnson; T. B. Read; and H. Young.

'GOLDSMITHS' INSTITUTE PHOTOGRAPHIC SOCIETY.

JANUARY 5TH.—With a view to giving a practical proof of the capabilities of "Griffin's Folding Enlarger," Mr. A. W. Green gave a demonstration of "Enlarging at Home." After indicating the great artistic value of the enlarged print when carefully executed, and briefly outlining some of the conditions which are essential to its successful production, among which he included the use of the new "Art Velox," with its lustrous surface and wide gradations, the demonstrator gave point to his remarks by a practical exposition of "the faith that was in him" in the shape of an excellent 10 by 8

bromide print which he made with Messrs. Griffin's Series "enlarger and incandescent gas attachment, in about 15 minutes." He also explained the commencement of exposure to developed print. He also explained the working of the three grades of enlarging apparatus which, marketed by his firm, viz., the Series "A," which is retailed at a price within the limits of the slimmest purse, the Series "B," somewhat superior form with more convenient attachments, and lastly, the Series "C," which is not only made with first-class materials and workmanship, but combines the "fixed focus" feature of the two previous patterns with a number of additional advantages, such as adjustable plate and lantern slide holder, automatic focus gear, and rack and pinion. This is really an enlarging, reducing, and lantern slide-making camera.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.

JANUARY 11TH.—Annual meeting, Mr. David Elliott, B.A., in the chair.

The annual report was read, and stated—"The president and committee, in presenting their annual report at the close of the nineteenth year of the society, have again the pleasure of announcing a satisfactory year's work. The members on the books at the beginning of year numbered 86. There were 9 new members elected during year; 13 lapses, resignations, etc., leaving a total membership at end of the year of 82. The committee have to record, with deep regret the death of one member, Mr. E. Bingham, for many years a prominent member of the committee. The general attendance of members friends has been very encouraging, and now that the society has well-fitted dark-room, easy of access (being on the ground floor), committee trust that same will be well availed of, and lead to increased membership. Your hon. secretary has been in correspondence with Mr. Liller, secretary of the Hotels and Tourist Association Ireland, re having dark rooms in hotels for the benefit of amateur photographers. Letters have also been received from the Registrar of the Royal Dublin Society, and the secretary of the Ulster Agricultural Association, Ireland, stating that amateurs have permission to photograph at shows of their societies. Through the kindness of Mr. Struver a medal was presented for competition among members, and your society had the honour of receiving a gold medal from the Lord Mayor of our city. It will also be a pleasure to the members to notice that of them, Sir Otto Jaffe, has been nominated as Lord Mayor for ensuing year."

The report was adopted.

The following were elected for the session 1904-5: President, Dr. Elliott, B.A.; committee, Miss E. Haslett, Miss W. Haslett, S. Allworthy, M.A., M.D.; Major-General Bland, R.E.; William Leary, J. W. Storey, B.A.; H. Struver; S. Clugston; hon. treasurer, J. Campbell Carson; hon. lanternist, C. Mitford Martin; hon. librarian, C. Mitford Martin; hon. secretary, Thomas N. Murray.

KENT AND LACEY, LIMITED.—This company has been registered with a capital of £10,000 in £1 shares, to acquire the business of Lyd Sawyer, Limited, of Singleton House, Northumberland Street, Newcastle-on-Tyne, and of Kent and Lacey, of 46, James Street, Harrogate, with a view thereto to adopt an agreement between Stainer (receiver of Lyd Sawyer, Limited), of the first part, W. Kent and S. Lacey of the second part, and F. G. Lundi (for this company) of the third part, and to carry on the business of photographic artists, photographic process, and general printing, photo-lithographers, art dealers, etc. No initial public issue.

At the technical meeting of the Royal Photographic Society Great Britain on Tuesday, January 26th, 1904, at 8 p.m., Mr. J. Sterry will read a paper entitled "The Separation of Development into Primary and Secondary Actions. Consequent Effect upon Correct Rendering of Light Values and Theory of the Latent Image." The following is the synopsis:—When a sensitive film is soaked between exposure and development with a solution antagonistic to developer, the gradation of the negative obtained is entirely altered, such alteration being largely dependent upon the strength of solution and the time of immersion. There is, however, a limit to action, the final result obtained being an entirely new scale, given under favourable conditions a closely correct gradation from the impression made to a point beyond the period of reversal shown in ordinary development.

Commercial & Legal Intelligence

Advertising for Pupils.—On Tuesday last, at Westminster Police W. Morris Crouch, otherwise Morris Beethoven, late of Ebury Imlico, was brought up in custody, on remand, charged with obtaining sums of money with intent to defraud. Ms. William Lewis, prosecuted for the Treasury, said the prisoner, who was a photographer, had advertised for pupils and assistants in a position to receive premiums and furnish deposits. The prisoner entered into agreement to undertake to make repayment of the deposits, but at the time his affairs were at the lowest pecuniary ebb, and there was no prospect that he would be in a position to meet his obligations. Alfred G. Cooper, of Richmond, said he paid the prisoner £50, and got into communication with him through an advertisement of an operator in a high-class London studio, with a view to a partnership. When the witness had deposited his money and entered upon his duties he found that there was no camera on the premises. Afterwards obtained, but no genuine business was done. The witness could not get his promised wages of two guineas a week, and was sent by the prisoner to collect the replies to many advertisements for pupils. The witness made repeated applications for the return of his deposit of £50, but could never obtain any portion of it. Robert C. Williamson, clerk, said that in September last he saw an advertisement in a daily newspaper. He had a conversation with the prisoner at Ebury Street. The prisoner said that he wanted some one to undertake clerical duties in connection with an employment agency, and that he must have a deposit of £50 as a guarantee of good faith. The witness consented to furnish this sum in two payments, and signed an agreement to act as the prisoner's secretary at a salary of £2 a week. The witness found his principal work was to answer advertisements in the photographic papers to solicit half-crowns "for register fees." He could not get his wages, and had never been able to get back one single penny of his £50 deposit. After some further evidence the prisoner was remanded.

Crystoleum Painting as a "Home Occupation."—So many of our ladies have been lamenting their lack of occupation and wishing for some home work, either for profit or amusement, that we thought we might suggest something which will be both profitable and amusing, but which, like everything else, will require application. Many ladies take up a piece of work, commence it, and then think it is too tedious, and throw it aside. Then they grow discontented because they have nothing to do, whereas if they would make a point of using up their old stores they would find many things to do. This kind of back and finishing up commenced work ought really to have been done before the commencement of a new year, and we would advise our young friends never to let the year close without completing all the work they have commenced since the beginning of the year. The work we have in mind is crystoleum painting, and would be pleasanter to ourselves and give more joy to our friends than being able to paint their portrait? Many girls will think, Oh! I have never learnt to paint. We can easily dispose of that objection by saying that it does not matter in the least whether you are able to paint or not. All that is required is a good photograph of a rather light tint, printed upon albuminised paper. Make a note of the colour of the hair, the eyes, and the complexion, and failure is impossible. Of course this, like everything else, requires a little knowledge. This knowledge may be obtained from Mrs. Alston, who has made a speciality of crystoleum-painting, and produced pictures just like beautiful painted miniatures. Mrs. Alston has had several competitions for the best specimens of crystoleum painting. Following on the success of last year, a competition was opened, which commenced October, 1903, and closes May 24th. There is no entrance fee in connection with this competition, and prizes are to be given in prizes for the best specimens. Surely, prizes are worth competing for, besides obtaining knowledge of this beautiful work. The materials required are neither expensive nor expensive. The complete outfit may be obtained from Mrs. Alston has hitherto been highly successful in teaching crystoleum painting by correspondence. If a guinea outfit is in mind, tuition is given free, and certainly this offer should be of advantage to you. You at once place yourself under the guidance of an experienced artist. A diploma is awarded for proficiency, enables pupils to become teachers, or to sell their pictures, if they wish, of increasing their incomes. As to the method itself, it is so simple and clear that anyone can master it.—"The Lady's

THE Photographic Association, Ltd.—A statutory meeting of the creditors of the above named company, against which a winding-up order had been obtained was held on Tuesday at the Board of Trade offices, Lincoln's Inn, W.C., under the presidency of Mr. Winearls, Official Receiver. The Official Receiver stated that the order for the winding-up of the company was made on December 1st. A statement of affairs had been filed by Captain Richardson, but owing to the incomplete state of the books he had been unable to prepare a proper deficiency account. There were forty-three unsecured creditors, and the total amount owing to them was £1,288 12s. 9d., loan debenture bonds £5,936. The assets were returned as follows:—Stock-in-trade, trade fixtures, etc., £200; goodwill valued at £250; book debts, good, doubtful and bad, £3,000, estimated to produce £1,500. Total assets £1,950. That amount was insufficient to the extent of nearly £4,000 to meet the debenture claims, so that there would probably be nothing for the unsecured creditors. The deficiency as regards shareholders was returned at £18,632. The Official Receiver continuing, said the company was formed on February 16th, 1899, with a nominal capital of £25,000 in £1 shares, and was formed to carry into effect a provisional agreement dated February 1st, 1899, to carry on a photographic club, and the business of dealers in photo requisites. The business was originally started by Mr. Le Couteur in 1896 at 18, Brook Street, Hanover Square, W. When the concern was sold to the company it was owned by Mr. Le Couteur and Captain Connop. Captain Connop had put £4,000 into the business. A short time prior to the formation of the company Mr. Cobbold put £1,250 into the concern for which he received a bill of sale as security. There had been various changes in the directorate, but at the date of the winding-up the directors were Captain Connop, Captain Richardson, and Mr. Wilson Burgess. Mr. Burgess said that was not correct, as he did not act as a director after January, 1903, when he was practically kicked out. (Laughter.) The property that was to be acquired under the original agreement by the company consisted of the goodwill, copyright in films, benefit of agencies and contracts, and interest in the leasehold premises at Brook Street, Hanover Square, and also certain freehold and leasehold premises at Hendon, the consideration being £20,000 in shares and £5,000 in cash. By a subsequent agreement entered into in March 1899 the agreement was adopted with the following modification. The property at Hendon was not included, and the payment of the purchase money was to be satisfied by the allotment of £20,000 in fully paid shares, of which £4,750 was to be surrendered in exchange for £1,250 first mortgage debenture shares, and £3,500 second mortgage debenture shares of £1 shares, the same to be secured on the whole of the assets of the company, and to rank *pari passu* with the ordinary shares in respect of dividend. No prospectus was issued in connection with the issue of the ordinary shares. The £20,000 worth of shares were allotted in July, 1899, and in addition to those shares £1,852 shares had been issued for cash, making a total of £21,852 shares. It would be a question for the liquidator to consider as to whether those £1,852 shares had been paid for. According to the directors' minute book the £4,750 shares were surrendered by Mr. Couteur, and were exchanged for mortgage debenture shares. Those debentures were issued to various persons, and a question would arise as to their legality. One of the directors Colonel Josiah Harris, who was appointed in 1902, complained that those debentures were issued to various people at board meetings to which he was not asked to attend, and a question would arise as to whether those board meetings were properly convened. The secretary of the company had sworn an affidavit in which he alleged that he was instructed not to write to Colonel Josiah Harris by one of the other directors. Mr. Burgess said he instructed the secretary not to write to Colonel Josiah Harris on the ground that at the time Colonel Harris was not a shareholder in the company, and therefore could not properly act as a director. The Official Receiver said the company was registered under "Table A," and it would be a question as to whether a director could not act without being a shareholder. Colonel Harris afterwards became a shareholder in the company, but not in 1902. In April 1903 Mr. Hayes, of Coleman Street, was appointed Receiver by the Court of Chancery, and he had sold the assets of the company with the exception of the book debts for £450. The purchaser was now in possession of the company's property. A debenture holder's action was pending and it would be necessary to test the validity of the debentures in

that action. It would also be necessary to draw the attention of the Court to the fact that Colonel Josiah Harris was not asked to be present at the board meetings at which those debentures were created. Colonel Harris said he objected most strongly to those debentures being granted, because he considered that it was taking away the assets from the creditors, with the result that the creditors would receive nothing. After a long discussion Colonel Harris moved and Mr. Chapman seconded that the matter be left in the hands of the Official Receiver, and this proposition was carried unanimously. At the shareholders' meeting a similar resolution was passed.

Correspondence.

PHOTOGRAPHIC WASHING.

To the Editors.

Gentlemen,—I feel reluctant to again trespass on your valuable space, but I must respectfully point out the serious compositor's error in the chemical equation of my last letter. The formula for sodium thiosulphate is $\text{Na}_2\text{S}_2\text{O}_3$, not as published NaS_2O_3 , which is as serious an error as the chemical equation I endeavoured to correct. The printed construction of the entire equation itself, with the water of crystallisation separate from the chemical molecule to which it attaches, is open to criticism. Another correspondent has the chemical formula for barium hyposulphite misquoted as $\text{Ba}_2\text{S}_2\text{O}_3$, instead of BaS_2O_3 . H.O.

—Thanking you for past favours, I am, gentlemen, yours truly,

January 18th, 1904.

FRED W. EDWARDS.

To the Editors.

Gentlemen,—Mr. Noton's letter, in your issue of 1st January, contains two errors. His $\text{Ba}_2(\text{S}_2\text{O}_3)$ should be BaS_2O_3 , and this salt is not barium sulphate, but barium hyposulphite. Soda hypo + barium chloride produce common salt and barium hypo.

"K," in your issue of January 15, says that barium hypo is "perfectly soluble in water." Mr. Edwards, in the same issue, says that it is "practically insoluble." Which is right? Will you kindly say?

If barium hypo is perfectly soluble I wonder, as "K." wonders, whence Mr. Noton's precipitate is derived, unless (as "K." suspects) his fixing bath contains sodium sulphite, which has turned to sulphate. In that case we have

If the two last of these salts interchange their molecules, we at once get Mr. Noton's insoluble barium sulphate and common salt, but unluckily the soda hypo, which was to be eliminated, remains instead.

If we use no sulphite in the bath, but simply get from the soda hypo + barium chloride, a perfectly soluble barium hypo + common salt, there can be no precipitate. But if the barium hypo can be perceptibly more easily and perfectly and certainly washed out than is the case with soda hypo, we have a very valuable improvement by Mr. Noton's method; only we must put no sulphate in the fixing bath, for fear of its combining as a sulphate with barium chloride.

I, therefore, have to ask you a further question. If barium hypo is perfectly soluble, can it be more quickly, perfectly, and certainly washed out than soda hypo?—I am, gentlemen, yours obediently

January 16th, 1904.

TREVOR GRANT.

[We shall deal with this subject next week.—Eds. B.J.P.]

THE IRIS DIAPHRAGM.

To the Editors.

Gentlemen,—With reference to your last leaderette, p. 42-43, I beg to observe that I was able to trace—in my theory and history, p. 97—the iris diaphragm back to the forties. Objectives containing

"une pupille artificielle" were sold by Ch. Chevalier, and Niepce is reported to have used such a device with his own. In the meantime I have found a notice of this idea at a still date. A short article, "The Iris Diaphragm, an Old Invention," Journ. Roy. Microscop. Soc., 1880, 3, 890—is quoted as taken from Nicholson's Journal, 1804 (exactly a hundred years ago). I have, ever, neither in a position to guarantee the correctness of the invention, nor to ascertain whether the idea of the iris diaphragm worked out practically at that time. But perhaps one of your readers will look up the source cited.—Yours truly,

MORITZ VON F.

Jena. January 16th, 1904.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—In reply to the rather impatient and somewhat impolite letter of Mr. Henry Oscar Klein, we beg to state that we have no desire to be drawn into any discussion about orthochromatic emulsion, since this can only resolve itself into an advertisement for Albert's emulsion, which is the only make on the English market that is actively pushed.

With regard to the announcement in your pages advising us to read our paper, we are, of course, not responsible for it. We have not the least idea who is. Mr. Klein's letter may perhaps have the clue. Can it be that he himself has had it inserted in your paper to serve as an introduction to his letter, and to commence a discussion for collodion emulsion?

On the other hand, perhaps it is due to ourselves that we have not entirely adhered to every statement made in our paper. We have compared orthochromatic plates, the result of no test has been published, except it had been confirmed by repetition. Repetitions being carried out over and over again in the collodion emulsion. With regard to the speed numbers, we did say "Account must be taken in all estimates of relative plate speed of the light used to test; . . . our test light was a W. mantle gas lamp,"* and they were only ascertained as a guide to make the photographic effect of our spectrum exposures nearly as possible actually correspond, so that one could say with absolute fairness the true relative sensitiveness of any plate or film. Supposing that our speed number for the C sensitised emulsion was higher, then we should have had to give a corresponding less exposure in the spectrum camera, and therefore its sensitivity to colour would not appear so good as it does. Mr. Klein has it both ways.

No one with a grain of common sense would expect to find the relative speeds of exposures to incandescent gas light would be the same as to the electric arc or daylight. New emulsion is given with the electric arc, and if it is desired to know the speed for arc light, then arc light must be used for the test. If ratios are required for three-colour work, then the filters must be used as well. It will be seen from this that our speed numbers have no direct connection with ratios obtained in practical work when using the electric arc and colour filters. Nevertheless, that when using a white light, such as the electric arc, the C sensitised emulsion is equal in speed to the A sensitised emulsion, as at present, when both are used exactly as directed, is simply and no amount of reiteration, either by Mr. Klein or anyone else, can make it true. With arc light reflected from white paper, the speed ratio of A to C is as 5 to 9, the A being sensitised immediately before use, and the C sensitiser added three days previously, as Mr. Klein suggests. If the emulsion is used immediately after adding the C sensitiser, it is very much slower than this. In three-colour work it is, of course, possible to make the speed under white light of the C equal to that of the A, but in two ways, first, either by using a weak colour filter for the red record, which would not give correct colour rendering, or by using a green colour filter that would be unnecessarily deep. With filters used here, which, though much less expensive, we find more accurate than Mr. Klein's, we find the exposure for the

* The Photographic Journal, October, 1903, page 266.

least six times that necessary for the A, and extra exposure, is experience of every operator we have ever met; even Mr. Klein self admits to three or four times being necessary. The only of the exposures being equal is when carbons cored with parlar earth giving red light have been used. This, of course, is giving the conditions. Shortly after our paper was read, we received a letter, informing us that Mr. Klein did not agree with results. We replied that perhaps this was a pity, but a matter of indifference to us. However, we offered to repeat the tests before Klein if he liked, or to give him the opportunity of himself giving the tests under the same conditions, with the same emulsion sensitiser as we had been using. Needless to say he did not accept of this offer, but, instead—will it be believed?—he actually makes tests, not with the same light that we used, viz., incandescent gas, nor the electric arc, as is used in practical work, with incandescent electric light, a light so yellow as to be utterly invisible. Then these tests unfortunately prove too much, for each square of the Chapman Jones plate tester means half as an exposure again as the preceding one, then instead of the C-tised emulsion being only equal in speed to the A, it is eight times faster!

A long course of respectful admiration for, and reverent handling of this wonderful product, has apparently caused Mr. Klein to delude himself into the belief that it is perfection. But no emphasis of will make us, or anyone else practically using the stuff, believe in the kind, for its variations are positively heart-breaking. At the same time, we do not shut our eyes to its possibilities. The results here have done work with it which will bear comparison with that done anywhere; indeed, we have this year put forward a three-colour block, negatives made by emulsion, in the "Process Book," and we are not ashamed to show the original of this in the reproduction. On the other hand, we have never seen anything in three-colour published by Mr. Klein, excepting an attempt at a spectrum in last year's "Year Book," of which we are not the least proud, as showing the excellence of the emulsion. In conclusion, we must again repeat that we decline to be drawn into any discussion for the purpose of advertisement.—Yours faithfully,

A. J. NEWTON,
A. J. BULL.

OVER-PRODUCTIVENESS IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—The article on "Over-productiveness in Photography" in your last issue is interesting, but like most of these articles I have in endeavouring to draw comparisons between the work of the painter and that of the photographer, to the detriment of the latter, a very important point is overlooked, or at any rate, disregarded, conveying a wrong impression to the general reader. In discussing the comparative merits of the two classes of workers, the painter is placed upon a pedestal occupied by such men as Turner, Millais, Leighton, etc., or at any rate, on such a lofty pedestal of superiority that he would never condescend to produce pictures alike, while the camera artists are referred to in such a way as to leave the impression that they are all of the "touch and go" class. This style of argument is misleading, because we are always hearing about a large class of beginners on the one side, and never hear anything about the tyros in the other class. One might imagine that there were no failures by students of drawing or painting; that they never committed glaring errors in composition, produced no artistic daubs, in fact, that they jumped straight into the elementary stage altogether. A few moments reflection on the matter will be useful and instructive. Why, for instance, do we hear so much of the Board School dabbler with paper and pencil, chalk and slate; or go a step or two higher, and visit the exhibitions of drawing and painting at the Technical schools, and the private schools in the country where these subjects are taught. Why, a large proportion of them would not find one purchaser, much less a second,

so that there would be no need to duplicate copies! Let us start fair in this controversy, and pit the thousands of elementary school daubers with pencil and brush against the equally elementary snapshotters who abound all over the country; while, as for the high-class workers, there is no more need for the Horsley Hinton, the Page Crofts, the Percy Lewises, the Craig Annans, etc., to break their negatives after the first production than there is for the first-class artists on canvas to break their brushes and easels. Good workers are scarce in each branch of art, and they will all want their brushes and negatives. Mr. Lockett, or anyone else, must not too readily assume that painters who have made a name in the world would not, or do not, produce copies of their famous pictures; it depends to a great extent upon the demand. An admirer of any particular painter who wishes to possess one of his works for mural decoration, would in nine cases out of ten, if there were not one already in the studio to his liking, commission the artist to paint one for him, merely specifying the class of subject; and so with the pictorial worker with the camera. The admirer of Hinton's works, for instance, desiring to purchase, would not probably be particular whether it were "Tide Bearer," or "Melton Meadows," or "Requiem," or a new one altogether, and the amount of brains and talent exercised in the production of a new or an old photo would not materially differ, for it is a great mistake to assume that extra copies of any particular success in pictorial photography can be turned out in a mechanical manner, merely because the worker may possess the negative.

In conclusion, then, to those who are about to take Mr. Lockett's advice and have a general smash-up, I would reiterate Punch's warning, "Don't."—Yours faithfully,

Park Close Studio, Corsham, Wilts.,
January 18th, 1904.

HERBERT SPACKMAN.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co, 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. C. H. BALMAIN, 69, Shandwick Place, Edinburgh. Two Photographs of the "Cinderella" Pantomime at the Theatre Royal, Edinburgh.
Cooper & Clift, Market Place, Boston. Photograph of St. Botolph's Church, Boston.
A. Webster, Bainton, Stamford. Photograph of "The Haycock" and Street, Photograph of the Church and Bridge—both at Wansford.

T. H. COPE.—If you communicate with Mr. T. E. Freshwater, 3, Fleet Street, London, E.C., he will probably be able to advise you.

SPOTS ON PRINTS.—F. NEWELL.—Particles of iron in the washing waters are a well-known cause of spots on prints. Attention has frequently been called to the fact in our columns during the past few months, though we thank you for your letter.

MANDARIN G'EXTRA.—W. BEVINS says: "I want to get some of the orange dye Mr. W. S. Davenport uses for his dark-room lamp light filter, as described in the 'Almanac,' and cannot meet with it at several places I have tried in London. You could not tell me, I suppose?" In reply: The Berlin firm have an agency in London. The address is 20, Eastcheap, E.C.

MOUNTING ENLARGEMENT.—J. H. says: "I should esteem it a favour if you would inform me the best way to mount a bromide enlargement 5 ft. by 2½ ft.? It would, of course, be put on a wooden stretcher, but should canvas first be fixed on stretcher, and then the print mounted on the canvas?" In reply: The canvas, or linen, should first be strained on the stretcher, and the picture mounted afterwards.

TITLE OF STUDIO.—G. E. C. says: "I would be glad if you would answer a question I am in doubt about. I am opening a studio, and I wish to call that studio Sandhurst Studio, because I am close to the Royal Sandhurst College, and because most of my work is with the college. Can I register that name, Sandhurst Studio?" In reply: You can call the studio by the name you propose, but you cannot register it under the Trade Marks Act.

STAINED NEGATIVES.—PRINTER writes: "Having spoilt several negatives by getting them silver stained in the rush for Christmas work, I should feel greatly obliged if you could recommend any way of removing the stain from varnished and unvarnished negatives." In reply: Some stains cannot be removed, while others can. Try a long immersion (some hours) in a new solution of hypo-sulphite of soda. Of course, the varnish must first be removed from the negatives which are varnished.

THE DAGUERRETYPE PROCESS.—A. OXLADE says: "Would you kindly give the working formulae for the 'Daguerreotype Process'?" Can the materials be obtained at present date?" In reply: It would take up far more space than we can afford in this column to give the details required for working this obsolete process, hence we must refer our correspondent to some of the earliest works on photography. We do not think it is possible that the silvered plates are to be had now, or the apparatus necessary for working the process.

COPYRIGHT QUERY.—COPYRIGHT says: "An assistant is sent to take photograph in House of Lords. The photo is copyrighted and sold. Afterwards I find that the assistant took two photographs without moving his camera. He keeps one negative, which is exactly similar to the photo I copyrighted. Does his copyright hold good by law? I cannot prove he used my dry plate, although I know he did."—In reply: As the assistant was paid by you for doing the work, he has no copyright in the picture. It really belongs to you.

DURATION OF COPYRIGHT.—H. L. MOREL asks: "Is it necessary to renew the registration, or does the original stand good, and for how long, and if I ought to be in possession of a paper showing that the above is entered at Stationers' Hall?" In reply: No renewal fee is required. The copyright lasts during the life of the author, and for seven years after his death. A copy of the entry in the register may be obtained at Stationers' Hall, E.C., by giving the date of registration, etc. The fee for a certificate is 5s. for each entry.

COPPER TONING—FILM.—PHOTOPHIL writes: "(1) A reference to a description of 'Mr. Ferguson's Copper Toning Process,' mentioned in the BRITISH JOURNAL OF PHOTOGRAPHY, December 4th, 1903, page 965, second column, sixth line, would much oblige. (2) Is there not some substitute for transparent celluloid film which is impervious to water, and perhaps also less inflammable?" In reply: (1) We answered this query for you in our issue for January 8th. (2) There is the "Cristoid" film, which is insoluble in water, but is not impervious to it. This film is not inflammable.

STUDIO QUERY.—S. L. FISHER says: "I propose building a new studio in a certain town. Would you kindly let me know if you are acquainted with a successful single slant light, where the studio is only 17 ft. wide? Personally, I think the double slant more suitable for a studio 33 ft. by 17 ft., but would esteem the favour of your valued opinion." In reply: There are very many studios with a single slant being successfully worked that are much less than 17 ft. wide. It is quite a matter of opinion as to which is preferable, the single or the double slant.

LENS QUERY.—J. G. HACKETT asks: "Will you kindly answer the following: (1) Zeiss convertible anastigmat, series VIIa, 23½

focus, f 12.5. (2) Cooke lens, series V., focus 18 in., f 8. So ining that (2) is working with a larger diaphragm and so much nearer the plate than (1), is it quicker, and to what extent? In reply: If the lenses are worked with their full aperture the No. 2 will be much the quicker. It will require less than half the exposure of the other. But if both lenses be stopped down to similar ratios, one will be practically as quick as the other.

ARISTOTYPE PAPER.—ARISTO writes: "Can you tell me who are the present agents for the American 'Aristo' paper in this country? I heard some time ago that one of their demonstrators paid a visit to Peterborough, but being situated somewhat away from the centre, he missed me altogether, and that is the very paper I have been interested in. So much so, in fact, that I sent to America three years ago to try and obtain it, and they replied saying they were sorry they could not send me samples and prices as requested, but their business relations with this country at that time were such that they were not in a position to handle the trade." In reply: The paper may probably be obtained of Messrs. Kodak, Limited, 43, Clerkenwell Road, London, E.C.

PHOTOGRAPHY IN AFRICA.—F. R. KEMPE asks: "Will you kindly give me your advice with regard to photography in South Africa? I understand studio work, and have been twelve months in a photographic studio. I want to be advised regarding going to Africa and starting a business. I thought of advertising for a partner who would come out with me. I want a man who understands retouching and finishing, as I am not much good at that branch, but thoroughly understand the studio work, etc." In reply: Personally, we know nothing about the present state of the photographic business in Africa except that there are some very excellent photographers there. We should think your best way would be to advertise for a partner you desire. We do not answer correspondents by post.

COPYING.—J. H. BALDOCK writes: "A friend has asked me to copy a very old parchment deed. The parchment is yellowed and more than half the writing has disappeared, leaving a kind of semi-transparent effect on the parchment, which has been eaten into numerous holes, and in places a good-sized piece has gone altogether. What I have done is this: I have tried to photograph it (vertically) lying on a flat board; lying on glass with a silvered glass reflector below it; and between two sheets of glass at a window, treating it as a transparency. I have tried slow plates and chromatic plates, also various forms of developers, and, of course, varying exposures. The results are unsatisfactory, as you will see by the enclosed print. Can you suggest any other procedure? If so, I shall be much obliged." In reply: Our correspondent has a very difficult job on hand, and we are afraid we cannot help him without seeing the deed. We might suggest, however, if the document is not too large, that a trial be made by contact printing.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

dye. If more light still be desired the focus may be shortened by adding highly refractive salts to the water. To those who desire an instrument for the expression of their artistic conceptions with more restrained alteration he recommends the use of two opera glass objectives of largest possible relative aperture. Mount them in a short tube with their flat surfaces turned to each other. This lens will be rather slower than the water lens, but although "not quite free from spherical, chromatic and astigmatic correction," should surpass the improved type of the Grün lens (fig. 130, in Eder's Jahrbuch, 1902) for astigmatic correction.

* * *

Lens v. Plate.

The article to which we have referred in the previous paragraph may, however, deserve consideration from a more serious point of view. If the optician has done much during the past twenty years to improve the quality of the photographer's work the plate maker has done more. The optician's task has been of much greater difficulty, which must not be overlooked in making this comparison, yet the plate maker has reaped the greater reward from the extension of the use of photography during that period. With the plates of extreme sensitiveness placed on the market during the past two years it may well be asked, what is the use of these lenses of exceptional aperture? For certain purposes, such as copying, enlarging, etc., they are of great value, but for general use $f/3$ is rarely wanted. We think the optician is well advised to subordinate rapidity to perfect definition. The opticians' task to increase the rapidity of a lens is an unattractive one, considered financially. It demands increased labour for a relatively smaller market, and he may well ask himself if the game is worth the candle. On the other hand, the plate maker who can produce a more sensitive emulsion, combined with other indispensable qualities, may look forward to a vast extension of business. The optician's market is suggestive of the returns from agriculture. To increase the rapidity of a lens the profit is smaller in comparison with the cost. So in farming, increase in quantity or quality of return can only be got at higher relative outlay.

A New Development Theory.

Dr. R. E. Liesegang has recently published a paper in which he states that for some time past he has worked upon the hypotheses, that chloride of silver, without free silver nitrate, is occasionally reduced to sub-chloride only by the action of a very dilute solution of hydroquinone, soda, and sulphite, with a considerable addition of potassium bromide. If metol be used, however, the chloride is immediately reduced to the metallic state. The coloured image in the fixing bath is assumed to undergo the following change. The hyposulphite of silver converts the subchloride to

21

EX CATHEDRA.

More light. Herr Karl Martin, of Rathenow, contributes an article to the "Photographische Mitteilungen," which may be looked upon as the utterance of an optician in his less serious moments. He reminds photographers that for more than fifty years they have had lenses with an aperture of $f/3$. The only improvement made in half a century has been the anastigmatic flattening of the field, which in the olden types is but imperfectly realised. The Planar, however, shows that this is possible with an aperture scarcely inferior to that of Petzval's lens. May not the question be asked, if the rapidity such lenses imply may not be taken as the practical limit, every step in advance becomes increasingly difficult? The Grün lens, for instance, appears to be of no value for obtaining fine definition at its abnormal aperture, since fluctuation of temperature affect the focus. Emil von Högh met with the same difficulty in 1895 or 1896, when calculating a lens in which alcohol was used. The instrument acquired a name which might have jeopardised the photographer, who used it after closing time. Herr Martin makes suggestions for the construction of lenses of exceptional rapidity, which may be of some value to those who are infatuated with emotional representations of the external world by diffused impressions upon a sensitive surface. The flask filled with water used by the dabbler to concentrate the light upon his work may be corrected for photographic use by adding a suitable violet

metal and chloride, and the latter is dissolved. The yellow, red, or otherwise coloured image of the finished print is a consequence of the minute size of the particles of silver. The subchloride predominates in proportion to the inactivity of the developer, that is to say, according to the quantity of water and bromide present or to the absence of alkali. To these causes may be added, as similar in effect, the restriction of the period of development, and the prolongation of the exposure. According to circumstances the image may be either yellow or red, without the slightest admixture of black. Prolongation of development or higher concentration of the solution will be productive of more or less metallic silver. In the fixing bath the loss of colour is greater in proportion to the yellowness of the image, but a black tone is not affected. The following experiment is offered as further confirmation. A yellowish red print obtained from gelatino-chloride, and a pure black print from gelatine bromide, were bleached with a solution of bromide of copper and washed. The prints were then exposed to daylight and redeveloped. Metol-soda immediately gave a black image, but hydroquinone, soda and sulphite with plenty of bromide, produced in both cases a coloured image. The original colour of the image could easily be renewed with the chloride paper, and the bromide paper gave a pleasing brown tone. Both the yellow and red prints again lost strength in the fixing bath, but the green and black did not. Dr. Liesegang does not hold that the theory is proved, and offers certain objections to it, but he holds to it as a working hypothesis.

In the Long Ago.

The extracts from the *Liverpool Photographic Journal*, the organ of the Liverpool Photographic Society (now the BRITISH JOURNAL OF PHOTOGRAPHY) of fifty years ago, which we gave our readers last week, and the week before, are interesting as showing the state of photography fifty years ago. From these extracts it will be seen that the art was far more advanced than many present day workers may surmise. For example, specimens of photo-lithography were shown at one of the meetings, as were also some photographic engravings on steel plates; so that neither photo-lithography nor photogravure is quite such a modern invention as many may imagine. One of the members of the Society showed a paper which was to be printed by gaslight, and yielded an excellent colour, so that gaslight papers are not altogether a modern idea. Another member of the Society endeavoured to persuade his fellow members to confine themselves to facts, without attempting to compete with the fine arts; while at the same time he laid down those principles of chiar-oscuro which are recognised as the essentials in works of fine arts for the benefit of those inclined to reject his advice as to the limits of photography. Here it will be seen that the limit of photography, as a fine art, was fully recognised half a century ago the same as it is to-day. The question was a vexed one then and it is still. At one of the meetings a member related that he had discovered that a weak negative by printing through blue glass would produce very effective prints. This is a method very generally followed now. We merely refer to these reprints of the old Journal to point out that our grand parents were not quite so benighted in photography, and its application, as many modern workers may have surmised. One thing that is noteworthy in connection with this old Society is the many new or improved apparatuses that were from time to time exhibited, and that not one of them formed the subject of a patent. One is almost inclined to speculate if that would be the case now-a-days when the most trivial thing seems to form the subject of a patent if its inventor thinks there is any novelty in it.

Micro-planar v. Ordinary Micro-objectives.

The controversy in our columns on this subject is one of considerable interest to those who give attention to the photographing of microscopic objects. The illustrations that have appeared have shown that in some cases one form of lens has yielded a better result than the other and in others the contrary. Now, it strikes us that, in comparing any two forms of lenses for any particular work, the excellence of the individual instruments, pitted against each other, is an important factor in the case, and this must not be overlooked. If the instruments are by makers of high repute they may be relied upon as being good, but some may be better in some respects than others, even if they are by the same maker. No high-class optician will let an instrument out of his place that is not up to his standard, but it does not follow that some he may issue are not something above that. Therefore, if a lens by a given maker of one form possessing superexcellence be compared with another of, say, normal excellence and of a different type, the comparison will not be convincing as to which type is the best. We know some old microscopists who pride themselves that they possess the finest "tenth" or "sixteenth" that A. or B. ever turned out, and they would not change it for any other by the same maker, and, possibly, they have ground for their opinion. What has been said with regard to microscopic objectives applies equally to photographic lenses. All lenses that are issued to the leading English opticians are carefully examined before they are sent out, and unless they pass a certain standard of excellence they are returned to the workshop for alteration, if not actually rejected entirely. But if the instrument should happen to exceed this standard of general excellence no alteration is made in it to reduce it to what we will term the standard of quality. Hence it follows that all the lenses issued by the first English makers—and they are but few—may be relied upon, yet some at times may prove in some respects slightly better than others; and so it is with microscopic objectives, and possibly to a greater extent. Therefore, as we have just said, any comparative tests of different types of lenses will, to an extent, be dependent upon the individual instruments themselves; also upon the class of subjects they are tested upon.

Are Residues Now Worth Saving?

This question engaged the attention of the Edinburgh Branch of the Professional Photographers' Association at its last meeting. One of the members wrote to the effect that for some time past he had been trying to recover the silver from old hypo baths, both negative and print fixing, and he had come to the conclusion that the results were not worth the time and trouble expended upon them. This opinion was endorsed by the members present at the meeting, but the majority of them were strongly of opinion that the saving of the cuttings of the silver papers, and precipitating the silver from the first washing waters of the prints prior to toning and fixing, was worth doing. Now, these opinions, coming as they do from a body of professional photographers, are well worthy of the attention of workers on a limited scale, who have been, and are being, at considerable trouble in saving their wastes, and have been at times sorely disappointed at the return they have had for them from the refiner. Only a few weeks ago we received a letter from a correspondent saying that he had sent four pounds of residues, and, after two shillings and a penny had been deducted for reducing, he received five penny stamps. In this case it is clear the "game was not worth the candle." At one time, when the collodion process was in vogue, and photographers sensitised their own paper on

long silver baths, the residues were a valuable asset in a large business. The used developer deposited a goodly amount of metallic silver; the washing waters, before using the prints, were rich in silver; and the old fixing baths, by reason of the papers being heavily salted, also contained a considerable quantity of recoverable silver. The conditions are just the reverse now. The developer contains no silver; the P.O.P.'s contain no more silver than is necessary to yield a good print, and that is very little indeed as compared with what was the case with heavily-tinted albumen paper sensitised on a strong bath. Bromide papers contain no free nitrate, and only enough bromide of silver to give a vigorous picture, and that, again, is very little, though ample for its purpose. The same with gelatin plates; there is sufficient silver in them to give a vigorous negative, but, after all, it is a very small quantity. Now, it is obvious that, as there is so little silver in modern plates and papers, there is very little to be recovered from residues from them. But this is not all when we take into consideration the low price the metal realises when it has been recovered. The present market price of standard silver is less than two shillings and twopence per ounce, whereas that recovered from photographic wastes is rarely up to the standard quality. At one time the price of silver was more than double what it is now. With the above facts before us it will be seen that it is very questionable whether it is worth the while of those who work on a small scale, or amateurs, to trouble themselves about saving their residues—that is, if time and trouble is a consideration.

ON MAKING SOLUTIONS.

There is one means more ready than another of finding a dark-room man of tidy habits it is either to scrutinise his shelves to see the condition of the various solutions in frequent use, or still better, to watch him use a bottleful of solution. What with stock solutions of pyro or other developing agents, solutions of soda, hypo, carbonate of soda, bromide of potassium in daily use, and ferridcyanide of potassium, uric chloride, ammonium persulphate, etc., in less urgent demand, it will be seen that a solution shelf may well be filled even for photographers in a small way. We should be careful that the knowledge of this fact has had much to do with the recommendation so frequently met with of "saturated solutions," the only good words for which that can be truthfully said being that they are a trouble to make. This is virtually the whole of the thing. "Saturated solutions," made by using an excess of crystals in the solvent and occasional shaking, are objectionable in many directions. With an overworked worker they rarely are saturated, and to a novice they are difficult to make really saturated. Their saturation is complete only at a particular temperature; and that, if allowed to remain undisturbed for some time, the material will crystallise out, which will also be the case if the temperature of the solution by any means varies, mixed, when more of the salt will be taken up and crystallise out again when the temperature gets lower. Again, supposing several stock solutions run out at the same time, what a loss of time to be continually making them, in order to get complete saturation. If, in most likely be the case, complete saturation be arrived at, the whole fabric of reliable and comparable solutions for various photographic operations falls to the ground, and the work is not very far removed from the state of "thumb." It is really most simple to keep solutions required strong at a given strength a little below

saturation; workers can then compare formulae from a definite standpoint, quite different from the inevitable confusion of a formula with "saturated solution." Of course, if it were a question of work carried on by expert chemists, they would have a fair idea of what proportion of salt, etc., would be contained in really a saturated solution, if a formula were put into their hands; but photographers are not all expert chemists. The confusion of mind that would arise at, say, a "practical evening" at a society, when, for example, one member should say there was nothing better than a 12 per cent. solution of sulphite for mixing with amidol as a developer, using the latter at 4 grains to the ounce; while another should say he greatly preferred to make it 8 grains to the ounce in a saturated solution of sulphite, and let it down with an equal quantity of water! As our readers will know, there is practically little difference between the two. The former would always be 12 per cent.; the latter would vary between 20 and 25 or 30, according to the temperature and mode of making. Further, still referring to a chemist's work, one would never think of employing saturated solutions unless the saturation carried with it certain advantages not possessed by weaker solutions, and this in photography is rarely, if ever, the case.

There is, however, in some quarters an unaccountable objection to the use of the term per centage to indicate definite proportions of substance dissolved; but this could easily be met by substituting such a term as grains per fluid ounce or ounces per pint, centigrams per litre, and so on. The root of the objection, however, is perhaps deeper, and through a want of thorough acquaintance with our somewhat involved system of weights and measures, the objectors are apt to see a lion in the way, the creation of their own minds. We never hear any objection on the grounds of indefiniteness if, for example, so many grams in a litre are spoken of, but the moment anyone speaks of grains per ounce, the usual fatuities of "Which ounce?" and so on, are heard, and per centage solutions are said to be meaningless. We appeal to our readers whether this sort of querulous objection is not common enough. We would like to make an effort to prevent their occurrence. First, we remind our readers that there is a legal measure of bulk called a fluid ounce. If we take that measure in water at a certain temperature, it happens that it will also weigh an ounce; but when "an ounce" of a liquid is specified, an ounce measure is usually implied. Hence a 10 or 20, etc., per cent. solution means one of which a measured 100 ounces contains 10 or 20, etc., weighed ounces of the substance specified. We will later bring our remarks to a more concrete form.

LORD RAYLEIGH has been created a foreign Knight of the Prussian Order Pour le Mérite for Sciences and Arts by the German Emperor.

THE third annual open exhibition of the Glasgow Southern Photographic Association will be held in the rooms of the Association, 1, Eglinton Lane, Glasgow, from March 22nd till April 5th next. There will be three open classes, one confined to members of the Scottish Photographic Federation and three confined to members. The prospectus will be ready shortly, a copy of which may be had on application to the Hon. Secretary, 28, Bank Street, Hillhead, Glasgow.

MESSRS. H. AND W. GREEN, of Rotherham, will shortly remove to new works, which they are now building in Rotherham. To reduce the stock of cameras, lenses, backgrounds, etc., and to save cost of removal, they are prepared to accept any reasonable offer for goods mentioned in a general or bargain list, which will be sent on application. The goods include thousands of developing dishes, printing frames, lantern slides, enlargers, stamp and midget cameras, dark-room lamps, albums, rubber type outfits, etc.

"COLOUR-SENSITIVE" VERSUS ORDINARY PLATES AND THE USE OF YELLOW SCREENS.

BEFORE proceeding to examine and explain the nature of the results obtained by the use of "colour-sensitive" plates, both with and without transparent coloured screens, compared with those given by uncorrected ordinary dry plates, it will be necessary, for the sake of clearness, to state a few facts about colour and its effects on the normal human eye.

White light, such as bright sunlight (daylight) consists, as most people know, of a mixture of lights of many different colours, known as the "prismatic colours," or colours of the "spectrum." We will assume that the reader knows this, and also how it can be shown to be true, by separating these colours by means of a prism of glass or other colourless transparent material, and by making white light again from these colours by means of a second prism so placed as to reverse the effect of the first. If some of the colours are partly or wholly cut out of the band of colours which constitute the "spectrum," the effect of recombining the remainder is a coloured light said to be "complementary" to those removed, and all colours of all shades consist of pure spectrum colours, mixed in various proportions, or very rarely of pure spectrum colours. Thus, the colour of a coloured transparent object, like a piece of stained glass, is the residue of the white light passing in, after the glass has "absorbed" the "complementary" rays of light. A red glass is red because it is capable of absorbing light of any colour other than red. Similarly, with coloured objects seen by reflected light, their colour is the "unabsorbed residue" of the light falling on them. If the light falling on them or a transparent "coloured" substance is itself coloured (i.e., deficient in any of the colours of the "spectrum" which go to make up white light), naturally that colour in which the light is deficient will also be missing in the light reflected or transmitted by the object. If, therefore, a coloured substance be examined by a coloured light, its apparent colour will change with that of the light employed. This is important in photography, because daylight varies considerably in colour at different times of the day and year, and contains much less blue and violet light (i.e., appears more yellow) at some times than at others, owing to the absorbing power of moisture, fog, etc., for blue rays. Blue haze, such as is often seen in hot, damp weather, owes its colour to blue light "reflected" by suspended particles, the yellow light complementary to it being transmitted or absorbed.

In reproducing a coloured object in monochrome, it becomes necessary to make up one's mind as to the relative brightness of different colours. For many people, and especially with some colour contrasts, this is by no means easy; but there can be no doubt that to almost everybody pure violet and deep blue are the darkest colours, and pure yellow the brightest, green, red, and orange being intermediate. Of course, any of these colours may be darker than any other if it be not pure but "degraded," i.e., if it absorbs a proportion of the light of its own colour as well as the complementary colours, or, in other words, if the coloured light returned is not returned in its entirety. The colours of Nature are nearly always more or less degraded. Turning now to the application of these remarks to photographic reproduction, it should be noted that all dry plates are sensitive to light of all colours. If this sensitiveness agreed with that of the eye in judging the relative brightness or tone values of different colours, we should have true "orthochromatic" plates. Unfortunately, this is very far from being the case. Ordinary (non-colour-sensitive) plates are so immensely more sensitive to blue and violet light than to light of any other colour that the blue and violet parts of white or other coloured light are

alone responsible for the effect produced by any ordinary exposure. All negatives made on "uncorrected" plates are representations of the blue-violet light given off by the object photographed, and no more. It is this fact which makes it so difficult to correctly estimate the exposure required; one has to estimate the intensity of the blue-violet part of the light, not that of the light as a whole; and, unfortunately, very large variations in this part cause comparatively little variation in the brightness of the light to our eyes. Long practice alone can guide us in our judgment.

Why, then, does not a picture taken on an ordinary (uncorrected) plate appear altogether false? There are several reasons. First of all, where the object photographed is devoid of colour, i.e., simply black and white and neutral half-tones, obviously, since it has no selective action on the light (i.e., it is not coloured), but the light simply varies in intensity, the different parts of the picture, it does not matter whether we make use of all or a part of the light only (the blue-violet), the relative brightnesses of the parts of the subject remain the same. This case, though not common, is often approximately true, colours, if present, not being prominent, or else very degraded. Secondly, all coloured objects reflect some white light (i.e., some of the coloured light which, in the main, they absorb, as well as the complementary colour proper, which they reflect well), and the blue-violet part of this reflected light has, of course, its usual effect. It may, and frequently does happen, therefore, that an object of a "colour" to which a photographic plate is quite insensitive with the exposure given produces a marked effect on the plate; this effect, however, is due solely to the blue-violet part of the reflected white light. One ought, therefore, to be very cautious in expressing opinion as to the colour-sensitiveness of a "corrected" plate from a simple test on opaque coloured objects. Lastly, although our eyes are very sensitive to differences of colour, our ideas on the relative brightnesses of different colours, and therefore the appropriate rendering of them in monochrome, are much less definite. These three considerations, together with the correct reproduction of form, combine to hide from us the false nature of the picture in a majority of cases.

There are, however, a great many cases where the colour contrast is so pronounced that its incorrect rendering by an ordinary plate would give a useless result; and even, apart from these extreme cases, a decided improvement in pictorial quality would often be obtained if colour were taken more into account. This a colour-sensitive (orthochromatic or isochromatic, etc.) plate does. Its action is as simple as that of the ordinary plate, but instead of being affected by blue and violet light only, it has a useful sensitiveness for light of other colours also.

From what has been said already, it will be obvious that the more sensitive a plate is to yellow and yellowish green (the brightest of colours), the more nearly will its reproduction of colour in monochrome be correct until, in a truly corrected plate, we reach a sensitiveness for these colours (relative to blue-violet sensitiveness), agreeing with our visual perception. Even the best green-yellow sensitive plates, like the Ilford Chromatic and Rapid Isochrom, do not respond sufficiently to these colours, but are still too sensitive to the blue and violet, though the gain by their insensitiveness to the blue and violet is in many cases enormous. These plates owe all their useful impressions to the effect of the blue and violet combined with the green and yellow, instead of blue and violet only, and, consequently, in estimating the intensity of light, and so the exposure required, we are not so liable to be misled as with an ordinary plate. In other words, we are to be guided more by the brightness of the light as it appears to the eye, and need not trouble so much about its "act-

quality," i.e., its strength in blue-violet rays. Where yellow and green objects form a feature of the picture, the "Chromatic" plates display their advantages at their best, and even orange and red objects produce much more effect on them than on an uncorrected plate. This is due, not so much to the greater sensitiveness to orange and red which Chromatic plates possess, or that is very small, but because red and orange-coloured objects generally reflect a good deal of green and yellow light.

In order to compensate for the excessive blue-violet sensitiveness, which is present even in "Chromatic" plates, a "screen" which filters out a part of the blue and violet rays is very convenient. Obviously, a yellow screen which almost completely absorbs the blue and violet rays, if used with an ordinary plate, takes away practically all the light of those colours to which alone such a plate is sensitive, and the exposure required must be so prolonged as to make the use of a screen impracticable. With a green-yellow sensitive plate this is not so, for a good yellow screen allows the green and yellow to pass without loss, and only the blue-violet part of the plate's sensitiveness is reduced. The more sensitive the plate is to yellow and green the less is the reduction of blue sensitiveness required to give correct rendering in monochrome, i.e., the lighter the tint of the yellow screen necessary, and conversely, with a given yellow screen, the greater the sensitiveness of the plate to yellow and green the less will the screen increase the necessary exposure.

It is, therefore, quite incorrect to imagine that a definite screen has a fixed slowing power, and one can therefore only speak of its "speed" in reference to a particular plate of a definite degree of colour sensitiveness.

Seeing how many dyes are available, it should now be quite possible to construct a number of "screens" adapted for use with a particular uniform brand of plate in all circumstances, and differing only in the amount of their correcting power. The nature of these screens will depend solely on the amount of correction desired and the increase of exposure one can put up with. Thus, a pale-tinted screen can be made which will reduce the intensity of the blue-violet until its effect on the plate relative to that of the blue-greens and light blues agrees with our ideas of their relative brightnesses. Of course, in doing this we also partly correct the brighter yellowish-greens and yellows, etc. In results obtained with such a screen the deepest blue-greens, blues, and violets will be approximately correctly rendered, but the yellows and brightest yellowish-greens, orange, etc., will still be too dark in the positive.

Fortunately, the relative sensitiveness of the Ilford colour-sensitive plates for the brighter blue-greens and yellowish-greens agrees very fairly well with our eye estimate, so that if we "correct" properly for one of them we correct for all.

To carry correction further, evidently all that is corrected by the first screen must be uniformly reduced until the bright yellow-greens attain their correct brightnesses relative to the deepest blue-greens, blues, and violets. In other words, besides reducing the blue and violet still further, we must also reduce what we have already corrected by the first screen, viz., the deepest blue-greens and light blues. It must have a slightly different tint, more golden yellow, than our supposed first screen. Another stage would be to correctly adjust for the pure orange-yellows as well. To do this we must now still further reduce all we weakened in the last case, and the yellowish-greens and bright greens as well. Such a screen would have a more orange tint than the last. The important point about all this is that it is a change of tint, as well as a deeper one, that is required in the successive degrees of correction, not a mere increase of the depth of the same tint. This latter at once leads to "over-correction," and is always the cause of that phenomenon; it shows itself as a practically complete insensitiveness to blue and violet, due to the complete absorp-

tion of these colours by the screen, while in many cases the yellows are still insufficiently corrected *relatively to the greens*. A screen which completely cuts out any pure colour must give "over-correction" for that colour, and the peculiar effects obtained on "colour-sensitive" plates when used with a deep yellow screen are due to this cause alone; the screen is at fault; it reduces the blue and violet too much while leaving the light blue and blue-green and greens unaffected. What is wanted is a screen of a pale orange or golden yellow tint which shall not reduce the deep blue and violet practically to extinction, as the strong, bright yellow screens do, but shall also somewhat reduce the light blue and blue-green. Similarly, a screen which is to correct for the orange-yellows as well as the greenish-yellows, greens, and blues, must not completely extinguish any of the latter colours, although, with all the colour-sensitive plates available up to the present, each of these colours would need reducing in intensity, and the screen would require to be more or less strongly orange or red in appearance. Screens correctly adjusted on these principles could not produce "over-correction" in any circumstances, though they would differ in the amount of their under-correction for yellow, orange, and red according to the extent to which the correction was carried.

STUDIOSUS.

SOME THOUGHTS ON COLOUR-VISION.

THE subject of colour-photography being at present much in the minds of photographers, the theory of colour-vision becomes of interest to those who are studying this branch of photography. The following somewhat random thoughts suggested themselves on reading some articles describing existing theories of colour-vision.

There seems to be an artificiality about the theories at present accepted involving assumptions of special nerves or "visual substances" which, apparently, physiologists have not yet succeeded in isolating, or detecting *in situ*. Taking the theory of Hering, where are the visual substances situated—in the retina, or in the brain? Obviously, there must be some mechanism in the retina itself to receive and differentiate the various colours; the bundle of impulses is then transmitted to the brain, where they are transmitted into sensations, and the mind perceives a certain resultant impression. The visual substances must, then, be situated in the retina, and we must suppose that every part of the intricate network of nerve-fibrils distributed through the retina contains all the visual substances.

It will be instructive to compare the method of working of the other sense-organs in this connection. Consider the immense variety of flavours distinguished by the sense of taste, and the endless series of odours reported by the olfactory nerves, from the delicate gratification of the rose's perfume to the jarring wrench of a puff of sewer-gas. How are all these varied properties recognised? It is impossible to suppose that the majority of flavours are the resultants of combinations of a few simple or elementary flavours. A vast number of distinct chemical substances have each their own characteristic taste which, once experienced, is always afterwards recognised. What mechanism can possibly sift out all the varied impulses corresponding to these numerous flavours, and transmit to the brain a message peculiar to each which, translated into brain-language, reveals a subtle property which would have been unknown to us but for the organ of taste? Is there a special "tasting substance" in the nerves of the tongue for every existing flavour? The idea is absurd. It is extremely probable that the peculiar property of a substance which is revealed to us as taste is a function of the molecule, and the nerves of the tongue are of but one kind and substance, responding by virtue of their subtle structure to each peculiar molecular vibration. Why, then, should it be thought that Nature would go out of her way to

elaborate new substances for the purposes of colour-vision when she had already evolved a material of so sensitive a character that it can distinguish an enormous number of minute molecular movements? It is true the movements now to be detected are ethereal and not material, and, since the molecules of different compounds are distinct in structure, they will be equally distinct in their vibratory or other movements. But although there may be no distinction in kind of vibrations of ether-waves corresponding to different colours, there is a difference of quality, namely in wave-length and number of impulses in a given time. A material or structure that can differentiate the vibrations of two such similar molecules as, say, potassium and sodium chlorides, may surely, without straining of analogy, be supposed capable of distinguishing varying periodicities of etheric undulations. But we are still left without an explanation as to how the brain translates these impulses into colour. This cannot be answered. We are quite unable to say why or how the vibrations impressed by molecules of sodium chloride on the nerves of the tongue should be translated by the brain into a sense of saltiness. It is so with all other sensations. Nor does it seem necessary to assume the existence in the brain of special visual substances, or special cells, to translate impulses of various periodicity into their respective colours. A man tastes for the first time some new fruit from a foreign country, and at once recognises a new flavour. Can it be believed that Nature had prepared in his brain, and in the brains of a long line of ancestors, special cells so that he might be able to taste this particular flavour when chance placed the fruit within his reach? Our common-sense rejects the notion. The brain that can, without special materials, translate unerringly into its appropriate taste-sensation a flavour never before experienced, may surely be relied on to construe correctly, also without special apparatus, each light-wave into the colour-sensation corresponding to its length and period. But, why a sensation of yellowness should result from the impress of light-waves having a length of 590 millionths of a millimetre, cannot at present be answered.

It would be interesting to study the subject of colour-vision in the light of the doctrine of evolution. At what stage in the evolution of man was this power developed? Probably far back in pre-historic ages; certainly not within historic times. The ancients knew and valued the purple of Tyre 1,000 or 2,000 years B.C. Since purple is a secondary colour, it is clear that an advanced stage in the evolution of colour-vision had already been reached at that epoch. Utility or fitness is the ordinary cause of the development of a new organ or power in the organic world. Cases of colour-blindness have been met with of such completeness that the vision of the subjects was practically mono-chromatic; yet these people were at no disadvantage in the practical affairs of life. Such facts point to a time when our ancestors had only mono-chromatic vision. They also suggest that colour-vision was acquired accidentally; some slight perception of difference of colours in some individuals was gradually accentuated by the dawning æsthetic sense in man, and eventually by cultivation the power was extended and fixed. How this power should contribute to the survival of its possessors is difficult to imagine, and from this point of view colour-vision ought to be largely the exclusive possession of a cultured minority. If the three-sensation or three-substance theory be the true explanation of colour-perception, it must have been at this period that the substances were elaborated. It may be imagined that some slight modification of the material of the existing nerve-tissue occurring in individuals enabled them to perceive differences of appearance in objects, which we now know as colour-differences, and these new, and at first crude, sensations adding to the sum of the pleasures of life were naturally cultivated, and thus in time the modified nerve-materials became fixed and definite and more perfect in their functions. All this

is not more difficult of acceptance than many of the hypotheses advanced to explain the evolution of various organic structures but the difficulty still remains why this power should have become so universal as it is. On the other hand, the existence of completely colour-blind persons is certainly, at first sight, a strong argument in favour of a special-substance theory, indicating the absence in such cases of a special colour-perceiving apparatus. But this would imply that the colour-perceiving apparatus is something over and above the merely visual apparatus. We are here reminded of Hering's white-black substance, for the perfectly colour-blind see objects in light and shade, and the explanation might be that they have the white-black substance while the colour substances are wanting. In this case the white-black substance would be merely the original substance of the optic nervous system before our ancestors had developed colour-vision, and the colour-pair substances are the modifications. This argument favours Hering's theory as against the Young-Helmholtz.

Other points of difficulty in Hering's theory suggest themselves, but the reasonable limits of an article of this character have already been reached. One may conclude by briefly adverting to one other apparent objection. There appears no reason why rays of light whose only difference is a slight inequality of wave-length should have such totally opposite effects on the same substance—destructive in the case of two particular colours, constructive in that of two others. Further, on the evolutionary hypothesis, it is difficult to see how modification of the original visual substance could acquire properties so profoundly different from those of the parent substance.

FESTINALENTE.

COMBINED DEVELOPING AND FIXING WITH CYANIDE OF POTASH.

"COMBINED Developing and Fixing" formed the subject of a very interesting paper read by Mr. Thorne Baker at the Royal Photographic Society a few weeks ago. Though the idea is by no means a new one, as was proved in the discussion that followed the paper, combined developing and fixing seems to open a wide field for experiment in photographic chemistry. The lecturer exhibited some very good slides as examples of plates developed and fixed in the same bath, but only claimed a partial success for the result of his labours.

The writer was surprised to find that, in both paper and subsequent discussion, hyposulphite of soda was the only fixing agent that was referred to by the speakers, even the use of wet-plate fixing solution of cyanide of potash not being mentioned. As the subject seemed to afford an opportunity for some interesting investigations, several experiments were made in combined developing and fixing, substituting, however, cyanide of potash for hypo for fixing purposes. Although hypo is now universally used by dry-plate photographers, most wet collodion operators still prefer cyanide of potash, the latter fixing agent being more rapid and clean in its action than that of the former, and the collodion film requires very little washing to eliminate the cyanide of potash.

The chief disadvantages in the use of cyanide are the excessively poisonous nature of this chemical and its higher price. A fairly strong solution of cyanide fixes a dry-plate very rapidly, and the plate requires little subsequent washing.

The writer's first experiments were made with the pyro-ammonia developer; this developer was only used for the purpose of observing the effect of cyanide on the developer. As cyanide of potash is a strong alkali, it would be thought that a smaller quantity of ammonia would be required, and accordingly operations were commenced with half the normal quantity

accelerator, about an ounce of a saturated solution of cyanide as added to four ounces of developer. The plate was fixed a few minutes, but not a trace of the image appeared.

It was obvious that the cyanide exercised a powerful restraining action on the developer, so the next plate was developed with twice the normal quantity of ammonia with less cyanide in the developer. A trace of the image appeared, but the plate was fixed before development had fairly started. The quantity of ammonia in the film was still further increased on the next plate; this time the image appeared quickly, and seemed to be developing properly, but when the plate was fixed a very thin picture with any amount of green fog caused by excess of ammonia was the only result.

For the next experiment amidol was selected, as the image with this developer flashes out very quickly it seemed to offer a better chance of success. The amidol was used dry, with a double quantity of sodium sulphite, but as the image failed to appear a small quantity of ammonia solution (Am. 2½ drms., water 20 ozs.) was poured into the dish, which immediately brought out the details of the negative, but the plate lacked density.

For the next plate an ounce of the ammonia solution was added as accelerator to the amidol. Ammonia with amidol gives a deep blue colour. Acetone and sodium sulphite kept this blue stain within reasonable limits, but the results on several experimental plates were not satisfactory, as the cyanide of potash prevented anything like density being obtained, and the ammonia produced a lot of chemical fog.

Pyro-soda, with three times the normal quantity of soda, and several drops of 880 ammonia, was then used. This was more successful, and with three drops of nitric acid to keep the developer from staining the plate (which with the large quantity of alkali was otherwise inevitable) a very passable image was obtained, being fixed and developed in about six minutes. The green fog was, however, very much in evidence on all the pyro-soda-ammonia negatives.

Pyro, in conjunction with amidol, was then tried. Pyro prevented the blue stain, caused by the use of amidol and ammonia, providing sulphite of soda was placed in the developer before the alkali was added. The pyro-amidol developer gave far more successful results than any of those previously mentioned. The proportions used were approximately as follows:—Pyro, 3 grains; amidol, 3 grains; sodium sulphite sat. solution, 1 ounce; sodium carbonate sat. solution, 2 ounces; ammonia 880, 3 drops; pot. cyanide sat. sol., about 1 ounce. A complicated and messy formula. Several variations of the above developers were tried, and the results were not by any means failures, and four plates developed and fixed with good printing density. Probably some of the other developers would have given still better results; metol-hydrokinone, for instance, seems to offer considerable advantages for combined developing and fixing.

The chief requirement seems to be a developer that brings out the image directly the developer is poured on the plate, and which will also give sufficient density before the image is fixed. Pyro alone did not develop the image quickly, and amidol gave no density, but the combination of the two produced very good negatives.

The plates when finished were evenly developed, and there were no weak spots in the image. The net results of the writer's experience is that though successful combined fixing and development would be well within the range of possibility, the simultaneous method would be more expensive in time, trouble, and money than separate operations. The subject is, however, of considerable experimental interest, and from this standpoint alone is worth the attention of photographers who like to wander from the beaten track.

Neither hypo nor cyanide of potash are ideal chemicals for combined developing and fixing, and probably some other fixing agent must be found if the single operation is to be commercially successful, but in any case the loss of control over the developing image would be such a serious drawback to the practical worker that probably it would be adopted only by the press-the-button type of photographer. In conclusion, we may remark that there is at the present time one branch of photography in which combined developing and fixing is successfully carried out with very little expense and trouble, viz., the ferro-prussiate printing process, in which the prints are developed and fixed at the same time in the same solution of H.O.

J. I. Pigg.

REMBRANDT PORTRAITS: A PHOTOGRAPHIC DISCOVERY.

(From the *Glasgow Herald*, June 22, 1867.)

"We have from time to time, during the last ten years, called the attention of our readers to the various advances which have been made in the art of producing pictures by the influence of the sun's rays acting on prepared silver, paper, and glass. The art of Sun-painting, whether we take into consideration the process known as the Daguerreotype, the Calotype, or Photography, is one of the most marvellous discoveries of modern times. By means of a salt of silver, and other chemical agents, the various substances we have named are rendered so sensitive to the solar rays that everything which the eye can distinguish, even when aided by a combination of the most powerful lenses, can be almost instantaneously depicted, and by other now well-known processes can be rendered sempiternally permanent. The extraordinary minuteness and brilliancy of the Sun-pictures now produced by the mighty host of practitioners of the art has ceased to be a miracle, but the surprising thing has always been that so little progress was made in the direction of giving a more artistic character to the portraits produced. It is true that photographic landscapes and sea-views have arrived as nearly as possible at perfection, but the photographic portraiture which meets the gaze in every city, town, and village of the empire, has not passed beyond the hard, formal, and cold stolidity which distinguished the first specimens exhibited in this country, from the studio of Daguerre himself. They are only sharper and more bright, but they have not acquired one atom more of artistic feeling.

"We are happy to have it in our power to inform all who take an interest in the progress of this very fascinating art, that now in this city an immense step has been made in the only direction wherein, as we think, improvement could be desired. This improvement, the discovery of Mr. Eadie, of the Minerva Rooms, Argyle Street, who is an accomplished painter of landscape pictures, consists in a novel arrangement by which all the softness and all the gradations of light and shade, which are so charming in some of the best painted and engraved portraits, can be perfectly rendered on silver, glass, or paper; and by which, at the same time, the portrait is produced with the proper aspect—not right for left and left for right, as has hitherto been the universal practice.

"For example, by the usual method, the camera delivers to the prepared plate all which the lens can take in—the face, the bust, the hands, and down to the feet and the carpet, if a full-length likeness be wanted; but there is no gradation of tone, no artistic distribution of light and shadow. Now, by the new process, a portrait is taken upon a plate; but, if we may be permitted to use such a form of expression, it seems to be thrown upon a cloud, because all round the head there is a white halo, and this light may be disposed at the back of the head or at the face at the pleasure of the operator, to suit the character

or the complexion of the sitter, and this aureola of light passes by imperceptible gradations of depth into a deep black, while the bust of the sitter is, so to speak, vignettied, passing from clear and bold lines into the obscurity of the dark shadow, which is the field upon which the portrait and its surrounding light are projected. By this novel arrangement, the concentrated light which Mr. Eadie throws upon his Rembrandt-Portraits, he shows as thorough a knowledge of pictorial effect as the camera itself exhibits of power to seize and transmit whatever is presented to it; and the powerful—we might almost say spiritual—pictures produced, evince in a high degree the artistic qualities of Mr. Eadie's intellect.

"The discoverer of these most admirable improvements has chosen to name the pictures so produced Rembrandt-Portraits, and in as far as they are pervaded by a very large amount of that breadth of light and shadow which distinguishes the paintings of the great master, we think the name appropriate enough. We have had an opportunity of carefully examining half a dozen of likenesses done after the new manner, and we can safely say that, for pictorial beauty and admirable arrangement of light and shade, they are superior by many degrees to any works we have ever seen produced by solar agency, and we can compare them with nothing save exquisitely-finished engravings.

"The Public had become almost surfeited with the cold and idiotic formality of photographic portraiture, but we think that Mr. Eadie's invention will at once elevate Sun-painting into the realm of high art, and therefore, it must, in his hands and after his style, become permanently popular."

MR. EADIE, PROFESSIONAL ARTIST,

Sole Inventor of the Direct Camera for producing Non-Reversed Portraits, etc., etc.,

Feels highly gratified in receiving daily public testimony of his Novel Invention, producing on Glass a Direct and Positive Portrait or Landscape, etc., representing everything in view in its true position. By the old method such is impossible, as Portraits, etc., coloured, were, and are produced to the public still, entirely the reverse of nature, such as showing the vest buttoned on the wrong side, the watch in the wrong pocket, the marriage ring on the wrong hand, and the sword of the soldier placed so as to be drawn with the left hand. These extreme errors are entirely avoided by Mr. Eadie,

at his

Photographic Studio, 249, Argyle Street, Glasgow.

DEVONPORT Camera Club. — The spring sessions commenced on Tuesday, January 19th, with a members' lantern evening, the slides exhibited included moorland churches, Dartmoor scenery, a holiday tour on the Continent, astronomical and scientific, those contributing being the President (W. H. Mayne), the Hon. Secretary (A. J. Catford), Engineer-Captain T. J. Haddy, R.N., and Mr. R. Maw. The lantern was manipulated by Mr. S. F. J. Heal.

G.E.R. 'MECHANICS' Institution, Stratford, E. (Photographic Section).—The eleventh annual exhibition will be held at the Mechanics' Institution, Store Street, Stratford, E., on Tuesday and Wednesday, March 8th and 9th, 1904. The judges will be Messrs. J. T. Ashby, F.R.P.S., and Ernest Marriage, F.R.P.S. The following are the open classes:—H. Any subject. Awards, one silver and two bronze medals. I. Lantern slides (sets of four). Awards, one silver and one bronze medal. J. Stereoscopic slides (sets of four). Award, one bronze medal. K. Not for competition. Exhibits invited. Fuller particulars may be had of the Hon. Secretary, Mr. A. Woolford, 16, Grove Green Road, Leytonstone.

SOME DISCURSIVE NOTES ON THE USE OF PLATES AND FILMS IN INDIA.

Specially contributed to the Journal of the Photographic Society of India.

"WHAT plates do you advise me to get?" is the question one often greeted with by the novice in photography. To answer such a question is but to name what one considers the best on the market for all round purposes. The writer's experience is as follows:—

(1) For a plate of medium rapidity for landscape and general work and capable of doing slow hand camera exposures Wratt and Wainwright's Instantaneous easily holds its own. For the purposes indicated above it appears perfect; it has keeping properties far in advance of any other plate in the market, and is essentially the plate for a beginner.

(2) As a faster plate for general hand camera work, and for any subjects where a considerable degree of speed is essential the Ilford Special Rapid plate gives most excellent results with a greater freedom from fog than any other plate which the writer has tried in India. Lumière's plates also give good results.

(3) When extreme speed is required, the Ilford Monarch plate should certainly be given a trial. Those who have already tried it speak very highly of its capabilities, and particularly of its very great speed and fineness of grain, the latter a peculiarity not often noticeable in very fast plates.

(4) Of isochromatic plates, the Instantaneous of B. J. Edwards and Co. will be found as good as any, and they will also be found to possess keeping properties of a nature not usually obtainable in isochromatic plates. These plates may be obtained ready backed under the description of "anti-halo"—this is a great convenience. Mawson's Iso. plates are also reliable.

A word here as to the keeping properties of isochromatic plates may not be altogether out of place: that isochromatic plates do not keep as well as ordinary plates in any climate is a recognised fact, and to this may be added a rider to the effect that a tropical climate, and particularly a damp heat, is most detrimental to their wellbeing. An iso. plate that will keep through a Calcutta rain under ordinary conditions has yet to be put on the market. It therefore behoves all users of these plates to be exceedingly careful as to the freshness of such they may purchase. It is somewhat outside the scope of this article to deal with the advantages to be gained by the use of plates of this type; their primary *raison d'être* is, of course a more correct rendering of colour values in monochrome and they are particularly valuable to secure the true rendering of cloud forms whether on the same negative as landscapes or not. The fact that these isochromatic plates and films are daily coming into more general use, as instanced by the Kodak Company discontinuing the sale of all but isochromatised films should be a valuable criterion of the merits of sensitive emulsions of this nature.

The question as to whether films will keep as well as plates in India during the hotter and damper months of the year has always been considered as answerable only by a decisive negative. The vast improvements which have been introduced into the manufacture of the former products during the last year or two, however, induced the writer to make a few experiments in the form of tests of some of the various makes of films present on the market, and it is the results of these test experiments that it is proposed to detail in this article.

Films may be divided into three distinct classes:—

(1) Those having celluloid as a supporting base.
(2) Cristoid films, which consist solely of a double emulsion of sensitive gelatine film.
(3) What are known as stripping films, i.e., single gelatin

films on paper supports, from which they can be easily stripped after development.

The first-named class may again be subdivided into two sections, viz., roll films and flat films, and it is proposed in the first instance to discuss the results yielded to the writer by these particular varieties of films. Several films of a number of each of the best known makes obtainable were placed in dark slides and kept there for over a week in the extreme heat of Calcutta in the middle of May, and the camera was then taken out into hot sunshine for a considerable time and the necessary exposures given to the films.

After a lapse of several days the films were developed in a dark room, the temperature of which was distinctly nearer 100 than 90 degrees, and in solutions which could only be described as tepid. No formalin bath was given before development, and no ice was used in that or any of the subsequent operations. The test was, as it was meant to be, a very severe one, and the writer was not in the least surprised to find that the majority of the films submitted to it succumbed at an early stage of the proceedings to the demoralising influences to which they were subjected. It was an ordeal to which one would have submitted one's favourite brand of plate with a considerable amount of fear and trembling, and the films gave way before it like chaff before the wind; there were, however, exceptions in the shape of two kinds of films which distinguished themselves by the creditable results they gave under the trying circumstances which have been enumerated. The films in question were the Mawson "Castle" and the Mawson "Celeritas," the former giving considerably better results than the latter. The remainder of the films experimented with were literally nowhere, many of them running off their celluloid supports shortly after as they came into contact with the developer. Such a state of things speaks for itself, and the reader may well be left to draw his own conclusions from the facts put before him.

The next test made was to all intents and purposes a second edition of the one described above, the only difference being that roll films were experimented upon instead of flat ones. The results on the average may be said to have been distinctly more satisfactory than in the former instance. Many of the negatives obtained were certainly a long way off perfection, but it would be possible to name half a dozen makes of films that gave results on which the makers have distinct reason to congratulate themselves. Ensign, Wellington, and Kodak films were perhaps about the most satisfactory, and gave results of about equal merit.

The severest trial of all was yet to come, however—the testing of the keeping properties of the films through the damp heat of the monsoon months—and it was here that the truth of the longstanding prejudice against the use of films in India was strikingly exemplified. It is no exaggeration to say that none of the films experimented upon—and they were many—gave really satisfactory results. Some were better than others, the roll films being distinctly in advance of the cut films, none of the latter, in fact, giving results which might be described as even passable.

Summarised, the conclusions, which may in the writer's opinion be deduced from the results of the above experiments, amount to more or less as follows:—

(1) Celluloid roll films can be worked in dry heat, and are preferable to cut films for the purpose.

(2) Films on a celluloid base are entirely unsuited for use under circumstances of extreme moist heat.

It may be safely assumed that the thicker the films the worse the result when tropical conditions of climate have to be taken into consideration; this is possibly because the thicker the celluloid base the more noxious gases it presumably gives off to the detriment of the sensitive film. This perhaps explains

why the thinner roll films possess better keeping and heat-resisting properties than their more substantial brethren. Or, again, it may be that the fact of the roll film being better protected from climatic influences by its tight packing preserves it from being affected by climatic influences to the same extent as the envelope-covered cut film.

Having disposed of celluloid films, it will be well to go on to the next variety on the list—Cristoid films. As previously explained, these films consist solely of a double emulsion of sensitive film. The two layers are of different degrees of sensitiveness, the lower one being of moderate speed and the superimposed film of considerable rapidity. The makers of these films claim two important advantages in respect to them in comparison with other films on the market. They assert them to be entirely devoid of halation, and that it is impossible, within reasonable limits, to so overexpose a film as to render it impossible to produce a good negative. Both these assertions have been found to be borne out by actual practice. The films keep admirably, and if the makers' instructions are faithfully followed appear to yield as good results throughout the year in India generally as the plates at present available. They are, however, in the writer's opinion, slightly more troublesome to develop than other films, but not sufficiently so as to deter any serious photographic student from at least giving them a trial; the two unusual properties alluded to above are worth considerably more than the extra trouble involved.

Stripping films, the last variety to be considered, can be dealt with in a few words. They consist of gelatine sensitive emulsion coated on paper, from which they are, after development, transferred to glass, from which they are stripped when dry. They gave very fair results in the writer's hands, and kept comparatively well in the hot weather and rains. A very fair amount of extra trouble is, however, involved in their manipulation without the compensating advantages obtainable from the class of films last described. The stripping films have, however, the merit of being inexpensive.

Regarding the use of films in the cold weather, it is fairly safe to say that any of the best known makes will give satisfaction if obtained fresh and treated with reasonable consideration. Of the isochromatic films on the market, it may be said that they possess similar properties to isochromatic plates of the same makes allied to the relative advantages and disadvantages of the emulsion being on a film support. B. J. Edwards and Co.'s Inst. Iso films and the new Kodak N.C. film are the most satisfactory films of this class tried by the writer.

THE WANDERER.

MISS GERTRUDE BACON gave a lecture before the Manchester Astronomical Society recently, her subject being "In Odd Corners with a Camera." Miss Bacon showed lantern-slides of photographs which she had taken from a balloon during aerial voyages with her father, the Rev. J. M. Bacon. These reproduced the appearance of towns and of crowds as seen from great heights, and included pictures of cloud effects. There were also photographs taken in the course of three eclipse expeditions upon which Miss Bacon had gone with other members of the British Astronomical Society. But the most interesting of the lantern views was one showing a photograph of the bottom of the sea taken from a balloon. In November, 1902, the Admiralty gave Mr. Bacon facilities to put to the test a theory that the sea, if looked down upon from a sufficient height, may be seen right to the bottom. If the theory proved to be correct, the Admiralty hoped that a way would be opened of discovering the submarine boats of enemies in time of war. Mr. Bacon crossed the Irish Channel, and from a height not stated he saw down to the bottom of the sea and made a photograph of the bed of the ocean. If a submarine boat had happened to be in that particular part of our home seas it would no doubt have been shown up by the photograph.

UPON CHANGING PHOTOGRAPHIC PLATES FROM THE DEVELOPER TO THE FIXING BATH WITHOUT RECOURSE TO THE DARK-ROOM.

[A Paper read before the Section of Photography and Microscopy of the Franklin Institute.]

(1) Let a photographic plate, which has been exposed in a camera, be developed in the dark-room in the usual way.

(2) After development place the plate under a tap of running water until the developer is thoroughly washed off.

(3) Open up the dark-room to daylight and place the plate in the fixing bath.

Fixation, without fog, will be complete in about ten or fifteen minutes, according to the strength of the bath used.

I was led to the above experiment by the fact that dealers are using developing machines in the dark-room to develop films because of the increased ease and speed by which films can be handled with the machine. Instead of putting the fixing bath into the machine, they withdraw the film after washing, place it in a tray containing a fixing bath prepared for a great number of films, and immediately proceed to develop a new film.

It at once occurred to me that it would be very important to devise a method of development by which the amateur, who has no dark-room, might be enabled to attain the speed of the dealer who has a dark-room.

The following experiments, (a), (b), (c), led up to (d), previously mentioned.

(a) Submit an exposed plate to the action of the developer, wash and fix in the dark-room, and the result will be a negative free from fog.

(b) Plunge an exposed plate, without development, into the fixing bath in daylight. After fixation the plate will be clear.

(c) Submit an exposed plate to the action of the developer in the dark-room, and in daylight, before washing, plunge it into the fixing bath. The plate will be fogged.

(d) Submit an exposed plate to the action of the developer, and, after washing off the developer in the dark-room, plunge the plate into the fixing bath in daylight. The negative will be found free from fog. (See *ante*.)

The developing machine is admirably adapted for just such an experiment. An exposed cartridge can be placed in it in daylight; can be developed in daylight; can be washed in daylight; and in daylight the carrier, black paper, and film can be unrolled, the film torn off from the paper and immersed in the fixing bath, prepared for a number of films, in another dish. In such an experiment I have found the negative to be free from fog. Thorough washing after development, and before exposure to the light, is the *sine qua non*. To obtain thorough washing after development, place the machine under a tap of running water, rotate the film, and frequently pour off the water until it runs clear.* Washing should be complete in about two minutes, and the machine be ready for the immediate development of another film.

Thus a method is pointed out by which the amateur, without a dark-room, may attain the speed of the dealer with a dark-room.

A. W. McCURDY.

DISCUSSION.

Mr. U. C. Wanner.—The paper of Mr. Arthur W. McCurdy, of Toronto, Canada, on the above subject suggested the following experiments:—

I exposed four Bradley's "Extra-Speed" plates twenty seconds each at U. S. stop 128 on a dull, cloudy morning in October, between 7.30 and 7.50 a.m., and a fifth plate two seconds at the same time and stop. The first of the four plates was developed as an over-exposed plate with pyrogallie acid developer, and fixed in the usual way, in the dark.

The second was developed precisely like the first, and when development was completed, was thoroughly rinsed under the tap and exposed to gaslight for half an hour, and then fixed in light. It was necessary to mark the plates to know which was fixed in the dark and which in the light. The third plate developed was the two-second exposure, treating it for under-exposure, after securing all

the detail possible, and developing the high lights almost to a harshness. I rinsed the plate thoroughly and exposed to gaslight for half an hour, then redeveloped the plate in a solution one-half the strength of the original until the entire surface of the plate was veiled that little detail could be seen in examination of plate by the ruby lamp. The plate was again thoroughly rinsed and exposed to gaslight for a considerable time, after which it was fixed in light.

The veiling of the film produced a much better printing negative than would have been possible without it in a plate so much under-exposed, by giving a better printing density to the entire negative, and especially to the shadows, without affecting the detail to any appreciable extent. This, of course, must be done with considerable care and judgment, as carrying the veiling too far would be at the sacrifice of brilliancy and detail; and again, this might be of use in securing diffusion or indistinctness for art purposes.

The fourth and fifth to be developed were treated precisely as the first and second, and, when development was complete, washed under the tap for a period not exceeding two minutes, after which they were dried in daylight. The fourth was fixed after being exposed to daylight an entire day, and the fifth was fixed before the Section of Photography and Microscopy on October 29th, 1903, after two days' exposure to daylight.

There is no apparent difference in the resulting negatives from the plates of same exposure and development, and the under-exposure was very materially improved by the heroic treatment given it.

These experiments fully bear out the claims made by Mr. McCurdy, and the conclusion is that a plate or film, washed free from the reducing agent used in developing the image, may be fixed as well in the light as in the dark, and at the convenience of the operator.

PHOSPHORESCENCE OF PHOTOGRAPHIC PLATES.

I OBTAINED the following results, writes Mr. T. A. Vaughton in "Nature," which are new to me, in the course of some experiments on the action of light on the salts of silver. I have not yet thoroughly examined the light or radiation emitted in these experiments, but its actinic power is low, and it appears to render the brush discharge from an induction coil more luminous. The sensitive silver salts, such as the bromide, iodide, and chloride, if precipitated and kept in the dark, have the property, under certain conditions, of emitting light in the degrees proportionate to their sensitiveness. Thus the bromide, which is the most sensitive, emits more light than the iodide and chloride. A convenient way of observing the phenomenon is to take a bromide photographic plate and place it at once (without having exposed it) in ordinary pyro soda developing solution and allow it to remain for ten minutes. Take out of the solution, wash, extinguish the "red lamp," and in total darkness plunge it suddenly into a dish containing a saturated solution of aluminium sulphate. The plate immediately becomes phosphorescent, and the solution also is luminous, but not so bright as the plate is at first. The light gradually weakens, and in a minute or two dies away. On pouring the solution off the plate into a bottle, the whole body of the liquid becomes luminous, and has the appearance of "bottled moonlight." It remains so several minutes, and the light is increased by shaking the liquid. If half the plate be exposed to the action of white light for a second before treating with the pyro soda solution, that half remains dark and emits no light when the plate is put into the aluminium sulphate. If the plate is given a short exposure in the camera, and developed and put into the aluminium sulphate solution, the image will appear dark on a phosphorescent background. On placing some precipitated bromide of silver (which had been kept a few days in corked test-tube in the dark) in a porcelain dish and exposing it to a bright red light whilst adding the pyro-soda solution, it appears black, but on pouring off the solution the precipitate gradually assumes a bright green appearance under the red light, whilst in white light it appears dark grey or black. The remarkable part of these experiments appears to me to be the fact that the exposing of the silver salts to the action of light destroys their power of emitting it under the treatment described, whilst the salt precipitated and treated in total darkness emits light freely.

* In this experiment I used pyrogallie acid developer.

Mr. H. J. Edwards writes to the same Journal:—"Some time ago when developing an X-ray photograph I observed the effect noticed by your correspondent. Very little of the silver salt had been acted, and the plate, after development, when put into alum solution lit up as described. I have often watched for the same effect with ordinary negatives; sometimes there is phosphorescence, sometimes not. Apparently a fairly long development with the pyro is necessary. Not only the plate itself, but the used developer I give the phosphorescence with alum solution. Dilute sulphuric acid may be used instead of the alum. Quinine sulphate or hydrochloride does not light up when the used developer is added, but it does if a few drops of sulphuric acid are subsequently introduced. Printing out paper may sometimes be successfully used instead of a plate, or the experiment may be still more easily made by mixing potassium bromide and silver nitrate solutions in dim gaslight, de-aerating, and shaking up the resulting silver bromide with pyro soda. The resulting liquid results which gives the lighting up effect when poured into alum solution or dilute sulphuric acid."

A PETERBOROUGH PHOTOGRAPHER'S BANKRUPTCY.

At Peterborough Bankruptcy Court on Friday last week, Harry Marriott, photographer, living at London Road, and lately carrying on business at the Eastmid Studio, Market Place, appeared before Mr. Registrar Gaches and underwent his public examination. There was statement of affairs on the file. Examined by the Official Receiver Mr. Howard W. Cox, debtor said he was apprenticed to the printing business at Wisbech. He studied photography himself, as an amusement first, and then he began business in Peterborough. Had you any money then?—No, only what my father lent me. How much did you have?—I cannot say. How long did you carry on that business?—The first business you had?—Twelve months. When was it you began?—I do not remember. Well you said here (in the statement by debtor) that you began in 1895. Is that correct?—Somewhere about then. What did you do at the end of the twelve months?—I took another business. What was it?—The same profession. Where?—The Cathedral Studio. In Peterborough?—Yes. Did you pay anything for that?—Yes. How much?—£100. Where did you get the £100 from?—From my father. You borrowed it from your father, or did he give it to you?—I borrowed it. Did you pay him back?—I think not. Don't you know?—Well, I have paid him the money back, but very little. Have you an account of how much you paid him?—I have not. How long did you carry on that business?—Five years. What happened then?—I built another studio. Where?—At my last place. Built it yourself?—Yes. How much did it cost?—About £200 or £300. Where did you get the money from to build that?—From my father. He lent it or gave it to you?—Lent. Did you pay him back?—No. Who was the studio to belong to at the end of the lease?—We were to renew it if necessary. You were to have it and glaze it?—No, I was not to do external repairs. That studio was to belong to the landlord?—Yes, in consideration of the lease and the rent I paid. What was the rent?—£40 per year. Did you get into difficulties at the end of five years?—I got into difficulties the first year I was in my new place. Did you call a meeting of your creditors?—I do not know I am sure. Did you execute a deed of assignment for the benefit of your creditors?—Yes. Who was the assignee?—R. W. Parr. Did you know what your liabilities were?—I cannot say exactly. Well, as near as you can tell me?—I think they were nearly £100. You said before they were £500, and now you say you were owing several hundred pounds to your father?—Yes, exactly, but not at the time you were speaking of. You said you borrowed £100 to get into the new studio.—I mean £100 beside what I owed my father. How much were they?—I cannot say now, it is such a long time ago. How much larger were they than you expected?—The Registrar: Is your father named under the assignment?—I cannot say. I had nothing at all to do with it really. The Official Receiver: What was the dividend?—I do not know. What became of the studio and the things in it?—They were sold to Eastmid and Co., Ltd. What was the Eastmid and Co., Ltd.?—It was formed out of the previous business. Who started the Eastmid Co.?—Well, Mr. Parr was Secretary. Yes?—And there were two or three directors, as far as I know; I was only acting-director of the business, and I did not do much of that work at all. Who paid for shares and found the

money?—I cannot say. Don't you know?—No; I know my father had some shares. What has happened to the Eastmid Co., Ltd.?—It was wound up. Who wound it up?—I do not know. What became of the Eastmid Co.'s goods?—I think the business was sold to my father. Did he give it back to you?—No, he sold me it. What did you pay him for it?—I do not think I have paid him yet. What did you agree to pay him?—£50 or £60. And you have not paid him?—No. How much have you paid him during the last twelve years, since 1892?—I do not think I have paid him anything. You told me just now you paid him some.—They would only be small amounts, borrowed suddenly and paid back in a few days. Have you ever had a business anywhere else?—No. Not in Leicester?—No. Never had a business anywhere at all?—No. As soon as the company was formed you began to incur debts again directly. You have been gradually getting into debt since the company was started?—I was working as manager then. You incurred debts yourself, didn't you?—Well, of course after the assignment we tried to pay everybody cash, and did not run into much debt. When was the company wound up?—It did not exist more than two or three years. You have been incurring debts ever since the company was wound up?—Yes. Could you pay them all?—I thought I could. Out of what?—Out of what I was earning. How much were you earning?—It varied in good and bad seasons. It has been £1 some weeks lately. When did you first begin getting summonses?—I have had them more or less ever since I made the assignment. That shows you were getting into debt, because you could not have been summoned unless you owed money.—You see all my old creditors did not come in. Well, they need not come in unless they like. So you have been insolvent ever since the deed of assignment, and you knew you could not pay your creditors in full?—Yes, if I had sold my business as a going concern I could have paid them. Yes, but you did not expect to sell it for much, did you? How much did you expect to get for a business which only brought in something occasionally?—Not very.—Why didn't you sell your business as a going concern?—Because I was hoping I should do better. If I had fine weather this year I might have pulled myself together. When did you buy a bicycle? The Registrar: The last one do you mean? The Official Receiver: Yes, the last bicycle. The Registrar: When did you buy your last bicycle?—No answer. The Official Receiver: Perhaps I should have put it that way. The Registrar (deliberately): When did you buy your last bicycle?—It would be about two or three years ago. The Official Receiver: I mean from Messrs. Robertson's?—Yes. Is that two or three years ago?—As far as I can remember. And what has become of the bicycle?—Sold. When?—About July, I think. To whom?—I don't know. It was sold on the Hill. What?—It was sold on the Market Hill. By whom?—It was damaged and was not worth repairing. Who damaged it?—It was worn out. Worn out?—Yes. But you had only had it about a year and a half or two years?—I must have had it longer than that. 1900 it was sold. You had had it something like three years.—Three years. Well, why worn out? My bicycle looks like new, and I have had it seven years.—This didn't. Why worn out?—I had to have it repaired several times until it got—You mean you broke it?—Yes, it was no use repairing it any longer. How much did you get for it?—25s., I think. You hadn't paid for it?—I had paid partly for it. No, you have not paid anything. They have proved for it now. The Registrar: How much have they proved for? The Official Receiver: They are proving for £3 0s. 9d., balance due to them. The Registrar: How much was the bicycle? The Official Receiver: £10. It is correct—he has paid part.—Debtor: And then there were contra accounts, too. Yes, I am including that. The contra account was £4 9s. 6d. Now, why haven't you filed your statement of affairs? The Registrar: Too busy, perhaps. (Laughter.) The Official Receiver: Why haven't you filed your statement of affairs? I did not know what to do. Oh, yes, you did. You were told what to do, and I have written a letter explaining to you what to do. Have you got my letter in which I told you what to do?—No answer. Why haven't you filed your statement of affairs?—Because I didn't know what to file. You didn't know?—I didn't know what to file. Where is the letter I sent you returning the statement you sent and explaining what you were to do?—It was at home. Why didn't you do what I told you? You have set out here a list of creditors. A great many amounts are not put opposite them. For instance, the Stamford, Spalding, and Boston Bank, how much do you owe them?—I really don't know. Do you

live in Peterborough?—Yes. Have you ever been past the Stamford, Spalding, and Boston Bank since the receiving order?—Yes. Couldn't you go in and ask them what you owed them?—Yes, I only put—Answer my question. Could you not go in and ask them what you owed them?—Yes. Did you do it?—No. Did you get a letter from me telling you to do it?—You suggested it. Why didn't you do as I asked?—I only put the name down—whether I owed them anything or not. Why didn't you go and ask them whether you owed anything or not?—No answer. The Registrar: That is a very loose way of doing anything. The Official Receiver: H. B. Vergette, ironmonger, Market Place—do you owe him anything?—I did owe him something before the assignment, and he did not come in. Why haven't you put the amount you owe him down?—Because Mr. Parr had all those. You have got to file your statement of affairs. If you don't know, why don't you go and ask Mr. Vergette what you owe him?—No answer. The Registrar: You see all those who did not come into the assignment are creditors now. The Official Receiver: Clarabut, Market Place, draper—no amount, and it does not say what the consideration was. Colls, Cowgate, the same; Dobson; Ellis and Everard; Edwards, Long Causeway. You have sixty-three creditors, and in hardly any cases are the amounts in; in no cases the debts and in no cases the consideration, all of which he could have ascertained if you had taken the trouble. The Registrar: Besides that, he ought to have known the amounts himself. It is a very loose way of going on. The Official Receiver: Of course he ought. He has not set out his rent. He has not set out anything. The Registrar: He ought to know his liabilities. It seems as if one doesn't care. Well, you must file—Debtor: I didn't want to make out a false statement. The Official Receiver: You did not make any attempt, although you had this back three weeks ago, telling you what you could do to make it complete. The Registrar: How long would it take him to make out this statement? The Official Receiver: Two days, if he worked. The Registrar: What are you doing now?—Debtor: Nothing. The Official Receiver: Two days, of course, would do it then. I would suggest a week. The Registrar: I will give him ten days. Debtor: What about those who live away? The Official Receiver: You must write to them.—And send letters through the post without any stamps? You must pay for the stamps. It is your statement.—Where am I to get the money from? How have you been living since the receiving order?—Eh? How have you fed yourself and drank yourself since the receiving order?—My wife has been keeping me. Then get your wife to find stamps.—I didn't understand it properly. You have been told, and I have told you, too, in letters which you can read and understand.—I have not been able to get at what the result of the assignment was. The Official Receiver: You have never tried. The Registrar: You could have gone to Mr. Parr and asked him; and your father would know. He was chairman of the company. The Registrar added that he would make an order that debtor file his statement within ten days. That would be ample time for a man who had nothing else to do. The Official Receiver: Is this statement in your own handwriting?—Debtor: Yes. What have you done to complete it since I wrote to you, and told you what to do?—I don't know. You have done nothing! I told you what to do—took the trouble to write a long letter to you explaining what you were to do. Mr. Craig tells me he told you, too, and you have done nothing. I had better tell the debtor at once (Mr. Cox proceeded, addressing the Registrar), that if he does not comply with your order I shall apply to the Judge to commit him for non-compliance with it. The Registrar: Certainly. It will be a serious thing for you if you don't file this statement. Debtor: I don't want to do anything that was detrimental. The Official Receiver: It is obvious he didn't want to do anything. Debtor: I went to Mr. Whitsea, the solicitor, and asked him. He said he would want a sovereign, and I said I could not afford that. The Official Receiver: I should think if you had drunk less during the last year you could have found the sovereign. It costs money to have beer and spirits and so on. The Registrar: There are other photographers in the town, aren't there?—Yes. They appear to get on, you know.—I think they are in a very

bad state. I should not say anything in public—what their business is. But I know trade is bad all over the country. And as drinking, sir, I have sometimes gone from morning to night without any food, and if I can't go in and have a glass of beer I cannot after my business. The Official Receiver: You have no right to that as long as you owe your creditors a penny. The examination was then adjourned.—*Peterborough Evening News.*

THE WORD "BIOSCOPE."

[*Tim's Report.*]

The case of the Warwick Trading Company versus Urban was cited by Mr. Justice Joyce in the Chancery Division of the High Court of Justice on Tuesday last.

The plaintiffs were dealers in cinematographic apparatus and film and by this action they claimed—(1) an injunction restraining defendants from infringing the plaintiffs' registered trade mark, word "bioscope"; and (2) an injunction restraining the defendants from passing off their goods as and for those of the plaintiffs. Defendants did not deny the infringement, but instituted proceedings by way of a cross-motion to expunge the plaintiffs' mark from the Register of Trade Marks, on the grounds—(1) that the mark had been entered on the register without sufficient cause; (2) that the word had reference to the character of the goods to which it was applied; and (3) that it was at the date of registration, or had since become, the name of the goods, and was therefore merely descriptive. The action and the motion came on for hearing together.

The plaintiff company was incorporated in May, 1898, for the purpose of acquiring and carrying on the English branch of a business theretofore carried on by a firm of Maguire and Baucus (Limited), New York and England. The defendant, Charles Urban, was at first employed in the American branch of Maguire and Baucus, and the formation of the plaintiff company he became one of their employees. The plaintiffs' business consisted to a great extent in the sale of a machine for projecting animated photographs on to a screen which machine they called the "bioscope." They also did a large business in films to be used in their machines, and in cameras taking negatives for the purpose of making the films. The plaintiff company did not themselves manufacture their goods, but had them made for them by other firms under their direction and supervision. In September, 1898, the plaintiff company applied for and obtained the registration of the word "bioscope" as a trade mark in respect of cinematographic apparatus for projecting animated pictures on a screen. It appeared that in 1903 the defendant Urban left the service of the plaintiff company, of which he had been the managing director, and commenced to carry on a similar business on his own account. He traded under the name of the Charles Urban Trading Company, and sold machines and apparatus like those of the plaintiffs, using the word "bioscope" in connection with his goods. In the circumstances the plaintiffs brought their action, which was met by the cross-motion of the defendant. Upon the motion the plaintiffs contended that "bioscope" was an "invented word" within Section 64 (1) (d) of the Patents, etc., Act, 1888, or, alternatively, that it was a word "having no reference to the character or quality of the goods" within sub-section (e) of the same section; and consequently that it was a good trade mark. The defendant, on the other hand, contended that the word was not an invented word, that it was a known name of goods of this description, and that the mark ought to be expunged from the register. Counsel on his behalf referred to various books or publications in which the word was to be found among them being the "Dictionary of Photography," the "Amateur Photographer" (1896), and the "Bioscope, or Dial of Life" (1891), while the word "bioscope" was indexed in the British Museum catalogue.

Upon this part of the case his Lordship held that "bioscope" was not an invented word, but was, in fact, a known English word. Further, it had been used in connection with apparatus of a similar character. He accordingly directed the mark to be expunged from

the register. Upon the other part of the case the plaintiffs contended that upon the evidence the word bioscope as applied to cinematographs and cinematographic apparatus denoted the origin of the goods—viz., that the goods sold under that name were the goods of the plaintiff company. They alleged that the defendant had, by his course of dealing and his catalogues, endeavoured to pass off his goods as those of the plaintiffs.

Mr. Hamilton, K.C., and Mr. Hodge appeared for the plaintiffs; and Mr. A. J. Walter and Mr. White for the defendants.

Mr. Justice Joyce, after stating the facts, said that before the plaintiff company existed the word "bioscope" was known in France as applied to a machine similar to that of the plaintiffs. An essential part of that machine had been patented in France and was protected in England, and both the plaintiffs and defendants paid royalties to the patentee. It was also shown that the word was known in America, and was to be found in various English publications. His Lordship then referred to the motion to rectify the Register of Trade Marks, and said that he had already ordered the mark to be expunged. The plaintiffs, however, endeavoured to maintain their right to a monopoly in the use of the word, in what was known as a passing-off action. The plaintiffs had amended their writ by asking for an injunction to restrain the defendant from representing that his business was the business of the plaintiffs. As to that, his Lordship held that there was no evidence to show that the defendant company had represented its business to be that of the plaintiff company. But an injunction was also claimed to restrain the defendants from using the word "bioscope" in connection with projecting machines and cameras without distinguishing the defendant's goods from those of the plaintiffs. But the plaintiffs were now calling their machines the "Warwick Bioscope," while the defendant called his the "Urban Bioscope." There was no danger of mistake, and no case of deception had been proved. His Lordship then referred to the judgment of Lord Herschell in "Reddaway v. Banham" (1896, A.C., 59), and to that of Lord Halsbury, Lord Chancellor, in "Birmingham Vinegar Brewery Company v. Powell" (1897, A.C., 710), where he said:—"The proposition of law is one which has been accepted by the highest judicial authority, and acted upon for a great number of years. It is that of Lord Justice Turner in 'Burgess v. Burgess' (D. M. and G., 204)—'No man can have any right to represent his goods as the goods of another person, but in applications of this kind it must be made out that the defendant is selling his own goods as those of another.' That is the only question of law which, as it appears to me, can arise in these cases. All the rest are questions of fact." The principal ground alleged by the plaintiffs for their case was that, by reason of the user of the term "bioscope" in connection with their goods it had come to denote their goods alone. In his Lordship's opinion, that had not been established. The plaintiffs were not entitled to the sole use of the word, and had no monopoly in it at all. The defendant's goods were sufficiently distinguished from those of the plaintiffs, and the action must be dismissed with costs.

The Röntgen Society's next ordinary general meeting will be held on Thursday, February 4th, 1904, at 20, Hanover Square. The chair will be taken at 8.30 p.m.

The Croydon Camera Club's Seventh Exhibition will be held at the Galleries, Park Lane, Croydon, from Wednesday April 6th, to Wednesday, April 13th, 1904. The judges will be Messrs. Frederick H. Mans, Frederick Hollyer, and Rev. F. C. Lambert, M.A. The following are the classes:—Restricted to Members: Section A (any subject)—Open to all members of the club. Section B (any subject)—Open to all members who have not gained an award at any of the club's annual exhibitions. Section C (lantern slides, any subject)—Sets of four. Awards will be given for the best sets. Open to members. Open to the World: Section D (any subject). Section E (lantern slides, any subject)—Sets of six. Awards will be given for the best sets. Entry forms and further particulars can be obtained from the exhibition secretary, Mr. C. Umfreville King, 1st Bank, Selsdon Road, Sanderstead, Croydon.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
29.....	West London Photo. Society..	<i>Mounting, &c.</i> Mr. E. T. Holding.
29.....	Nottingham Camera Club	<i>Photograph and Rotogr. Papers.</i> Demonstration. Mr. W. A. Sims.
29.....	Aberdeen Photographic Assoc.	Jumble Sale.
29.....	Watford Photographic Union	Members' Lantern Slides.
30.....	Glasgow Southern Photo. Assoc	Last date for sending in Entries for the Championship Cup and Lantern Slide Competitions.
Feb.		
1.....	Southampton Camera Club.....	<i>The Photographic News</i> , Prize Slides.
1.....	South London Photo. Society	<i>Colour Photography for Moderate Means.</i> Mr. T. Thorne Baker, F.C.S., F.R.P.S.
1.....	Bowes Pk. and District Ph. Soc.	Lantern Slide Competition.
1.....	Oxford Camera Club	Annual General Meeting.
1.....	Ilford and District Photo. Soc.	<i>A Ramb's Through Epping Forest.</i> Mr. H. T. Mally, F.R.P.S.
1.....	Camera Club	<i>A New Departure in Connection with Control Printing.</i> Mr. Nelson K. Cherrill.
1.....	Glasgow & W. of Scotland P.A	<i>Recovering Residues.</i> Demonstrator, Mr. W. G. Buchanan.
1.....	Burton-on-Trent Photo. Soc.	Lantern Lecture, "Majorca."
2.....	Royal Photographic Society	<i>Bromide Printing.</i> Demonstrated. Mr. G. Winthrop Somerville.
2.....	Glasgow Southern Photo. Assoc	<i>Stereoscopic Photography.</i> Mr. W. B. Hosack.
2.....	Aberdeen Photographic Assoc.	Annual "At Home."
2.....	Rotherham Photo. Society	Printing Papers—P.O.P., Bromide, Gaslight.
3.....	Croydon Nat. His. and Sc. Soc	<i>Ancient Entrenchments.</i> Anthropological.
3.....	Photographic Club	Open Night.
4.....	Bath Y.M.C.A. Camera Club	<i>A Few Practical Hints to Amateurs.</i> Mr. S. Curvis.
4.....	Southport Photo. Society	<i>A Cycle Tour in the Lake District.</i> Illustrated. Mr. J. T. Rigby.
4.....	Glasgow Southern Photo. Assoc	Last date for sending in Prints to the Federation Exhibition at Perth.
4.....	Liverpool Amateur Photo. Asso	Competition Pictures on view.
4.....	London & Prov. Photo. Asso.	<i>The Decimal and Metrical Systems.</i> Mr. J. R. Gotz.
4.....	Richmond Camera Club.....	Lantern Night.
4.....	Watford Camera Club	Photographic Evening. Mr. H. Wood-Smith.
4.....	Hull Photographic Society	<i>Photography Prize Slides.</i>
4.....	Dundee & E. of Scotland P.A.	<i>Gum-bichromate.</i> Demonstration. Mr. G. D. Macdougald.
4.....	Gainsboro' Camera Club	<i>Amateur Photographer Prize Prints.</i>
4.....	Camera Club	<i>Amiens and its Cathedral.</i> Rev. T. Perkins, M.A.

CAMERA CLUB.

ACCIDENTS will happen, even at such a well regulated establishment as the Camera Club, and on Monday last week the expected lecturer, Mr. Egerton Castle, was obliged by force of circumstances to beg off. But a most admirable substitute was found in the person of Mr. Henry Stevens, who had kindly consented at very short notice, to bring a selection of his beautiful pictures and to talk about them.

In these days of so-called "pictorial" photography, which is too often the excuse for unlimited faking of both positives and negatives, it is quite a relief to turn to the kind of pictures which used to be regarded as the best. The type of picture which we mean was one which owed its being to an intelligent use of the camera and lens, coupled with the artistic instinct which prompted good choice of subject and correct lighting. There was no dodging of any kind. Mr. Stevens is one of the foremost exponents of this kind of photography. He has always aimed at the highest technique, and he manages to hit his mark. At the Camera Club on Monday night he showed on the lantern screen nearly two hundred pictures, and he was able to say that he had never retouched or altered a picture in the whole course of his career. Another still more curious statement was that he had never used an isochromatic plate or screen. Considering that he has produced such a variety of beautiful flower studies this is very remarkable, and many will suggest that he would have done better had he adopted these modern aids. But looking to the lovely and tender tones which Mr. Stevens secures upon the petals of these studies the impartial critic is led to ask himself how they could be improved. With regard to the animal studies it is at once evident that they would have been impossible under the extended exposure which would have been necessary with an efficient screen.

One of the secrets of Mr. Stevens's success is liberal exposure with

a small stop, coupled with partial development so as to bring out everything upon the plate. And it is quite evident that he must possess an enormous stock of that invaluable photographic ingredient called "patience." We should like to see the expression on the face of the average professional photographer if he had brought to his studio a basket containing live rabbits, cats, kittens, and a fox terrier, with instructions to make a good picture of them in the studio, and to take care that none of them moved. Mr. Stevens possesses the secret of accomplishing this, and not once in a while, as a fluke, but over and over again. He said that it often involved three entertainments going on at the same time, and he had all kinds of music to amuse the animals. One would like the sackbut, another the dulcimer, and so on.

The lecturer also showed a number of very successful portraits of different members of the club, and Mr. Frank Braine was very anxious to know in what manner the photographer had secured their attention, and whether the attraction provided took the form of liquid refreshment of any kind. Flowers, animals, portraits, curios, alternated with one another in marvellous profusion, and Mr. Stevens showed that he was a most versatile workman with the camera. On the motion of the chairman of the evening, Mr. T. C. Hepworth, he was accorded a most sincere vote of thanks.

On Thursday, the 21st inst., there was an interesting lecture by Dr. Von Recklinhausen, on "The Mercury Vapour Lamp and its Application to Photography." We some months ago described this lamp in our columns, and therefore it will be unnecessary to enter into minute details concerning it. It is being pioneered by the Westinghouse Company, and we believe that anyone who wishes to see it in action can do so by applying to them. The lamps shown at the lecture consisted of two, each requiring a 50 volt current, and giving together a most brilliant light, by the help of which several portrait negatives were secured by Dr. Grün with his liquid lens. An improvement has been made in the lamp since last we referred to it. Its form is that of a glass tube, about two feet long, exhausted of air and containing at one end a bulb containing mercury. This tube is so supported that it can be tilted, when the mercury naturally runs to the lowermost end, makes the necessary connection between the two terminals, and the light is immediately established. In the older form of stationary lamp an initial current of high intensity was required to bridge over the space before light could be had.

It will be evident to those who have only slight electrical knowledge that the mercury vapour lamp resembles a Geissler tube. But the light given out is far more powerful than any apparatus of the kind which has been yet brought forward.

It is not a pleasant light, for the red rays of the spectrum are absent from it. Examined with the spectroscope we find bright lines in the blue, yellow, and violet regions, and a mixture of these colours gives a light of very peculiar tint. One gentleman who was present declares that it made the living face look like that of a corpse—and a dirty corpse, too—"one that wanted washing." But in spite of this drawback the light is found very serviceable for photography.

The lecturer gave a brief historical account of the efforts to obtain a light from mercury vapour, and claimed that this lamp—known as the Cooper-Hewitt—was the first one which was practical and commercial. The lamp as at present made is only workable on a continuous current installation. The light given is rich in ultra violet rays, but unfortunately these do not get outside the lamp, for they are screened off by the glass. Experiments are now in progress, with a view to use quartz or some kind of special glass which will pass ultra violet light. The unpleasant tone of the light, which might frighten ladies away from a photographic studio, can be modified by screening it with red silk, which has been treated with a fluorescent dye. The lamp is claimed to have a far higher efficiency for a given current than any other form of electric illumination. The lamp has found favour in America with process block makers, who use two 50-volt lamps, supported on suitable stands, upon each side of the drawing to be copied. It is absolutely steady in action, never flickers, and the radiance afforded is of a constant kind. It is also used for general studio work and for printing negatives.

Particulars regarding this latter employment of the lamp will interest our readers, for the dull weather experienced for many months must have made many of them wish for some source of efficient artificial light. The lecturer said that a landscape negative which would require ten minutes to print in direct sunlight, on a June day, and thirty-

five minutes to print it in diffused daylight, would require under the arc light eighty minutes, and under the Cooper-Hewitt mercury lamp only twelve minutes. This high efficiency of the mercury lamp is due, not only to its activity, but also to the circumstances that the glowing tubes can be brought close against the printing frames.

We suppose that never before was a lecturer assailed with such torrent of questions as this one had to answer. And we regret that we cannot afford space to consider them. Before the close of the meeting Dr. Grün was able to show the results of his portraiture. One taken in half a second at F. 5 was fully exposed, and one to which ten seconds was given, with a red screen behind the lens, was considerably over-exposed. Dr. Grün explained that this particular red passed the yellow rays, and the picture showed the value of such rays to the photographer. The lecturer, although he was speaking not in his own language, was singularly clear in all his explanations, and was much thanked by those present for his admirable demonstration and discourse.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 21ST.—Mr. Rapson in the chair. The hon. secretary announced that the supper (February 18th) would be served at 7.15, not 7.30 as announced on tickets. Mr. S. Rawkin gave a lecture on "Some Lantern Slide Methods," fully illustrated with examples of building up pictures and sky of general and local reduction with hypo and ferricyanide, of local and general toning as a means of obtaining colour. A pleasant and instructive evening was spent, and the lecturer was heartily thanked for display of skill and ability.

CROYDON CAMERA CLUB.

JANUARY 20TH.—A somewhat novel demonstration was provided for this evening, Mr. Hickox, the originator of the Quta Ferrottype Camera showing this ingenious little machine in actual operation, in combination with the platinotype portrait lamp, the latter being in charge of its inventor, Mr. W. H. Smith, who, in addition, manipulated the camera "to the manner born," though his acquaintanceship with it had been of short duration.

Between twenty and thirty photographs of the members were taken in what appeared to the uninitiated, to be an incredibly short time, on minute precisely being the period necessary to focus, expose, develop, fix, wash, and dry the resulting "tin-type." This, of course, could only be achieved by reducing each step to a semi-mechanical operation. The lamp itself standardised the exposure, $7\frac{1}{2}$ grains of magnesium ribbon forming one charge, and the mechanism of the camera did the rest, excepting a brief wash, and hasty drying over a special spirit lamp attached to the tripod. The Quta may be broadly stated to consist of three compartments, the camera proper being one, a magazine of 36 ferrottype dry plates alongside being another. After focussing the screen it slid on one side, and a dry plate automatically occupies the focal plane. The third compartment is underneath, with two narrow tanks, ranged one behind the other, containing respectively the developing and fixing solutions. After exposure a lever is pulled, the plate drops through a slot into the developer, or rather into a movable dipper contained therein, and after a brief immersion is removed by the clipper into the fixing solution. Fixation is complete in a few seconds, and the plate taken out briefly washed and dried. The camera is so light loading, and provision is made for taking both upright and oblique pictures. The whole apparatus packs up into small compass, and its construction is such as to stand a considerable amount of wear and tear. Focussing is achieved by a simple sliding motion, which, not so convenient as a rack and pinion, is perhaps less likely to get out of order. It is claimed for the Quta dry plates that they are a step in advance as regards speed, and Mr. Smith bore out this contention, but, compared to a modern fast dry plate, they are extremely slow. With a stop approximately F. 6 out of doors in the shade, 2 to 3 seconds is required, according to circumstances. Indeed, Mr. Hickox stated that until Mr. Hector Maclean had drawn the platinotype portrait lamp to his attention, he had been unable to find any artificial light of any practical value, though he had scoured Germany and the United States in the quest. Flash lamps placed close and with a small charge would do the work, but the dust had to be got rid of somehow.

An exposure of 17 seconds to the two powerful arc lights had resulted in under-exposure.

Mr. Hickox, in the course of his remarks, stated, with some natural complacency, that he had secured the sole rights for ferrotype photography at the forthcoming St. Louis Exhibition, and proposed planting over one hundred machines in the grounds and buildings. Presuming the operator attached to each machine to be a pushful canvasser for custom, no difficulty, to say the least, should be experienced by visitors in having their features nicely recorded on tin.

MANCHESTER AMATEUR PHOTOGRAPHIC SOCIETY.

The following are extracts from the nineteenth annual report. During the year we have held what is intended to be the first of a series of open photographic exhibitions in the North of England, and we are every reason to be proud of the results of our efforts. In conjunction with the Leeds Camera Club and the Liverpool Amateur Photographic Association we have established a rota by which there is to be an open photographic exhibition held in the North each year, at Liverpool in 1904, Leeds 1905, Manchester 1906. This year council confidently hopes will stimulate not only our own but all the photographic societies of the North, and will also tend to the advancement of photography in general. Notwithstanding an open exhibition in March the annual exhibition of members' work in November was up to and even surpassed its previous high standard of excellence. Last year we were startled to find that 64 meetings of the members had been held in one year, this year the number is 80, which includes 5 evenings at the Athenæum, 47 at the Society's rooms, and 17 rambles. If we counted the eight evenings of the open exhibition we should have a grand total of 88. At the last annual meeting we had 335 names on the roll of membership of the Society. During the year we have elected 71 members, making a total of 406. Against this we have to record the loss by death of two members, of 39 through removal or resignation, and of nine struck off for non-payment of subscription. The net membership of the Society at this meeting is 356, an increase of 21 members.

LIVERPOOL AMATEUR PHOTOGRAPHIC SOCIETY.

At the last meeting the president announced the result of the annual competition as follows:—Prints.—Championship—Class A (gold medal and trophy), Mr. Joseph Appleby; Class B (silver medal), Messrs. J. Crichton Timpany and Charles Gostenhofer; Class C (silver medals), Messrs. C. E. Langtry and H. E. Cubley; Class D, no competitors; Class E (bronze medals), Lieut.-Colonel John Pilkington and Mr. Alex. Wands. Ladies' Competition (silver medal presented by president).—Miss Laura Harvey. Lantern Slides.—Class F, championship (gold medal and trophy).—Dr. C. Thurstan Holland; Class G (silver medals), Messrs. James Petree and W. Mallinson. Bi-monthly competition for the highest number of prints gained during the year.—Mr. Charles Quinn (silver medal) and Mr. H. Holt (bronze medal).

DUNDEE AND EAST OF SCOTLAND PHOTOGRAPHIC ASSOCIATION.

JANUARY 14th.—The Dundee and East of Scotland Photographic Association is fortunate in having located in the same town a University College, and doubly fortunate that it finds members of the faculty there willing to prepare for them lectures so delightful that which Professor Kuenen delivered. The redoubtable battery of apparatus on the platform indicated at once that no ordinary treat was forthcoming. Business was quickly despatched, and the meeting at itself in the hands of Professor Kuenen and his assistants. "The Nature of Light" was the subject announced, and a series of beautiful experiments were given indicating the wave motion and the electric qualities of light. The recent lecture on "Radium" in the Innaid Hall had familiarised members with the electroscope and the fact that it could be discharged by the radium rays. The demonstration by Professor Kuenen that a beam of light had the same power was therefore watched with great interest, especially when it was shown that a piece of ruby glass, or even ordinary plate-glass, cuts off the ultra-violet rays and robs the light of its electric fluence. The effect of fog in splitting up white light into its four components gave a useful hint to photographers, and the

concluding experiment brought out our old friend hypo in a new guise. The disintegration of hypo-sulphite depositing sulphur particles in the path of the light was shown as producing on the screen the effect of the setting sun. The comment on the various experiments was made with rare grace and humour.

Patent News.

The following applications for Patents were made between January 11 and January 16, 1904:—

Printing Frames.—No. 681. "Improvements in photographic printing frames." Complete specification. James MacSheehy.

Coloured Photographs.—No. 808. "New and improved process for producing coloured photographs." Walter Riebenschalm and Gustav Koppmann.

Films.—No. 866. "Improvements in the method of using photographic films and in means therefor." Edward John Gammage.

Washing Films.—No. 896. "Improvements in and relating to means for washing photographic films and the like." Wilfrid Lean.

Films.—No. 925. "Improvements in films for use in photography." (Actien Gesellschaft fur Anilin-Fabrikation, Germany.) Charles Denton Abel.

Changer.—No. 922. "Improvements in means for holding and for facilitating the changing of photographic films and plates." Conrad Beck.

Printing Frames.—No. 998. "Improvements connected with photographic printing frames." Alfred Eustace Marriott.

Coloured Photographs.—No. 1,008. "A new or improved method and apparatus for the production of coloured photographs." Charles Julius Drac.

Sound Indicator.—No. 1,017. "Sound indicator for cameras and the like." Walter J. Levi.

FORTHCOMING EXHIBITIONS.

February 10-13.—The Longton and District Photographic Society. Hon. Secretary, T. Mottershead, 43, Stafford Street, Longton, Staffs.

February 13-27.—Scottish National Photographic Salon. Exhibition Secretary, Alex. Mackenzie, 42, Scott Street, Perth.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Chadwell, Essex.

March 5. Last day for entries February 18.—South London Photographic Society. Entry forms from W. Calder Marshall, F.C.A., 41, Glenton Road, Lee, S.E.

March 5-12.—Brechin Photographic Association. Hon. Secretary, J. Kirk, 1, Infirmary Street, Brechin.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

DANGERS of Hydrogen.—Alfred Allchin, employed by a Greenwich firm of iron merchants, died in hospital at Greenwich on Monday week from injuries received through an explosion on the Saturday. He had placed a cylinder of hydrogen gas near a wood fire on the premises of his employers, and the cylinder burst with tremendous force.

Commercial & Legal Intelligence

Messrs. A. E. Staley and Co., are this week removing to larger and more convenient premises in the centre of the optical trade, situated at 19, Thavies' Inn, Holborn Circus.

The Leto Photo Materials Company, Limited, has been registered with a capital of £2,000 in £1 shares (1,000 six per cent. cumulative preference). Object, to manufacture and deal in photographic materials and goods, etc. No initial public issue. Registered office, 9, Rangoon Street, E.C.

Messrs. W. Butcher and Sons, of Camera House, Farringdon Avenue, London, E.C., write:—We have taken over the business of Messrs. Bessus and Co., of 84, Hatton Garden, E.C., including goodwill, patents, stock, workshop, and plant. We shall be transferring the whole of the wholesale business, including the stock, from 84, Hatton Garden, to Camera House, but for the present intend to carry on the workshop at Hatton Garden. We have secured the services of Mr. Bannister, the late proprietor, as an additional London representative. All orders and correspondence, therefore, for Messrs. Bessus and Co. should be addressed to Camera House instead of Hatton Garden.

BEFORE Mr. Justice Channell and a special jury at the Suffolk Assizes at Ipswich last week Mr. George Quilter, of the Bath Hotel, Felixstowe, sued Mr. Arnold Wright, editor and registered proprietor of the "London Argus," for damages for loss of custom alleged to have been suffered owing to the publication in plaintiff's paper of a photograph which gave a view of some stables as the plaintiff's premises. Mr. Kemp, K.C., and Mr. Poyser appeared for the plaintiff; and Mr. Dickens, K.C., and Mr. Boydell Houghton for the defendant. Defendant published an article on Felixstowe, with illustrations which were intended to give views of the new Felixstowe Hotel and of the Bath Hotel, but only stables appeared in this second illustration, and plaintiff claimed that in the next three months he lost £700 of custom by the misrepresentation. Evidence of a falling-off was given by an accountant who had examined the books of the Bath Hotel. In defence, it was explained that Mr. Arnold Wright took the photograph himself, and thought that he had included the Bath Hotel. He did not personally develop the negative, and when the "pull" of the block was sent to him it was not sufficiently clear to reveal the fact that the Bath Hotel had been left out of the picture. He afterwards inserted an article and illustrations giving prominence to the Bath Hotel. Mr. Dickens argued that the small building shown in the first picture could never be mistaken for the Bath Hotel by any reasonable being, but Mr. Kemp urged that an editor who did injustice through carelessness should pay compensation. The jury gave a verdict for the plaintiff with £50 damages, and judgment was entered for that amount and costs.

THE Woodford Photographic Society's tenth annual exhibition will be held at the Wilfrid Lawson Hotel, Woodford Green, on Thursday, February 4, 6.30 to 10 p.m.; Friday, February 5, 6.30 to 10 p.m.; Saturday, February 6, 3 to 9.30 p.m.

NEW PLANETS.—Three new planets have been discovered by Herr Dugan at the Observatory at Königstuhl, near Heidelberg. One of them may possibly turn out to be identical with an asteroid already known, but the others are certainly new. The discovery was made by photography.—"The Standard."

ROYAL PHOTOGRAPHIC SOCIETY.—Tuesday, February 2.—Second of the series of practical demonstrations on printing processes, "Bromide Printing," by Mr. C. Winthrop Somerville. Synopsis—(1) Why a preference is given to the bromide process. (2) The formation of a working and definite base to reduce uncertainty in the process to the lowest possible limit. (3) The negative. (4) Correct exposure. (5) Development. (6) Variations of exposure and development. (7) Developers. (8) Bromide of potassium. (9) Toning. Demonstration.—Enlargements and printing in of clouds. Sepia toning with sodium sulphide.

News and Notes.

RADIUM in Germany.—A mining expert at Freiberg, in Saxony, states that radium is to be found, not only at Joachimsthal, on the Bohemian side of the Erzgebirge, but also on the Saxon side, as by-product of silver ores. Substances containing radium have been found at Vereinigteld, in the Forsten Mountains, near Johannsgeorgenstadt, in Saxony. The uranium pitchblende, the production of which is very costly, and which was formerly used in the preparation of choice green and yellow colours for porcelain painting, is likely to become once more a very valuable substance, and the object of extensive mining operations.

REPORTED Discovery of Radium in America.—Several Professors of Princeton University concur in giving precision to the report regarding the discovery of radium in America, secured, not from pitchblende, but from carnotite, a canary-coloured ore, the supply of which is practically limitless. It promises to be equal in quality with the product secured by M. Curie, and to be infinitely less expensive. Carnotite abounds in Utah. It contains oxides of uranium and vanadium. Experiments lasting a year have resulted in the establishment of works on the Curie process on a large scale at Buffalo.—"The Standard."

THE President of the Board of Trade has appointed the following gentlemen, Lord Rayleigh, F.R.S. (chairman), Sir William de W. Abney, K.C.B., F.R.S., Dr. Robert Farquharson, M.P., Mr. William King, and Mr. J. Fletcher Moulton, K.C., M.P., to be a committee to inquire and report as to the statutory requirements relating to the illuminating power and purity of gas supplied by the metropolitan gas companies, and as to the methods now adopted for testing the same, and whether any alteration is desirable in such requirements or methods, and, if so, whether any consequential alteration should be made in the standard price of gas. Mr. Herbert C. Honey, of the Board of Trade, has been appointed secretary to the committee.

WRITING on Blue Prints.—In connection with the use of alkaline agents for writing in white on blue prints, one frequently sees this solution mentioned, but always with the disappointing statement that the solution will blur by spreading through the fibres of the paper. I have thought it might be of interest to such of our readers as are using blue prints to know of a method which I have used for some time with entire success, consisting of mixing the blue with a more or less thin gum arabic or mucilage water. Oxalate of potash (10 per cent. solution) is about the only alkali that will produce a pure white and satisfactory mark.—W. F. Moody, in "The Scientific American."

PETER COOPER HEWITT, the inventor of the vapour lamp, has recently been granted a patent on a new form of his lamp. Up to the present time the lamps have been constructed for installation in vertical position, but the inventor has discovered that by placing the lamps in a horizontal position a number of practical as well as aesthetic advantages are secured. The lighting of the room is said to be accomplished in a much more satisfactory manner, and the quality of the light is improved. Mr. Hewitt has also been granted a patent on an improvement in the construction of the lamps, which the starting of the lamp is facilitated at a much lower potentiality. This is done by the addition of red sulphide of mercury to the interior of the lamp during the course of construction.

ANTHROPOLOGICAL Photographs in India.—With a view to making the photographs of independent inquirers, travellers, collectors, museum officials, and others, generally available to those interested in Anthropological Science, who would not otherwise be able to obtain them, for the purpose of comparison or inquiry, the Council of the Asiatic Society of Bengal have decided to adopt for India a similar method to that which the British Association for the Advancement of Science has adopted in England. The Council have decided to establish a depot for the registration and storage of Anthropological photographs at the Asiatic Society's building. Anyone who possesses photographs of anthropological interest, is therefore invited to send one unmounted print of the same, which will be mounted by the society, together with particulars of the photographs sent, as noted in the annexed form, and

also to state whether he is willing to deposit the negative with the society. Measures will be taken for keeping all negatives so deposited carefully and in good order, but the society cannot hold themselves responsible for the negatives although every possible care will be taken. The society will also arrange to have prints made when required, at the lowest possible rates, and the price at which a copy of any photograph can be so obtained will be entered in the list that will be published by the society. The copyright of all such photographs will, of course, remain the property of their owners, and this will be clearly stated whenever any prints of them are supplied on application.

Radium and Light Waves.—Some results of an investigation into the photographic action of radium radiation were laid before the Physical Society's meeting last week by Mr. S. Skinner. The object of the research was to trace out how far the photographic influence was comparable with that of ordinary light, and the conclusions gained brought out several important points in the connection between the ultimate nature of radium and ordinary light waves. It was found that when ordinary photographic plates were exposed to the influence of radium bromide the intensity of the image produced increased rapidly with a longer time of exposure, then decreased gradually until a stage was reached when practically no dark image was formed on development. A striking resemblance is here found to ordinary photography, where, as is well known, over-exposure involves a fainter image. Further, there seemed little doubt that the impression was produced by the β and γ rays only, for the α rays must have been absorbed by the mica plate that was interposed. This would appear to point to a definite advance in the solution of the problem now before physicists, viz., whether any real modification of the prevailing wave theory of light would be demanded by further elucidation of the nature of radio-activity. A still further resemblance in the radium influence and that of ordinary light lay in the observation that a plate that had been exposed to the bright light of an electric spark, if further exposed to radium bromide underwent a complete reversal in the image. This was precisely the same phenomenon as that observed by Claydon, who obtained a reversal of the electric light impression by weak gas light. The final conclusion seemed to be, therefore, that there was a fundamental connection between the β and γ rays, the intensely rapid and minute particles of Crookes and Thomson, and the so-called waves of sunlight.

AN "Arts and Crafts Exhibition" will be held in the Music Hall, Shrewsbury, from March 15th to 15th inclusive, under the presidency of the Earl of Powis, Lord Lieutenant of the County, and under the influential patronage of the Duchess of Sutherland, Lord Berwick, the Countess of Bradford, Colonel Hon. F. Bridgeman, Lady M. Cholmondeley, the Dowager Lady Corbet, Sir W. Corbet, Bart., Lady C. Milnes-Gaskell, Mr. H. D. Greene, M.P., Lady Harnage, General Hon. W. H. Herbert, Lady Mary Herbert, Mrs. Noel Hill, Lord Kenyon, the Hon. Mrs. Leeke, the Hon. Mrs. Heywood-Lonsdale, Lady G. Monckton, the Hon. Mrs. Ogilvey, Colonel Kenyon-Slaney, M.P., Lady Mabel Kenyon-Slaney, Lady Stamer, Lady Stokes, the Hon. and Rev. G. H. F. Vane, Sir Offley Wakeman, Bart., and many others. A committee has been formed, of which Mrs. Atherley, of Attingham Park, is the hon. treasurer, and Mrs. Mather, of Meole Brace, Shrewsbury, the hon. secretary. Prizes amounting to a considerable sum are announced, limited to Shropshire. The method adopted in the division of the classes of exhibits is one which should bring out all the latent talent in the county, with the best possible results. The last day for entering exhibits or applying for space is February 14th. The authorities at South Kensington are preparing to lend a large and valuable collection of objects to illustrate in other ways the same class of subjects as those exhibited by the competitors, and other things of a highly interesting and educational character. Many well-known craftsmen from a distance have already applied for space to show their handiwork, not for competition. Besides these there will be many articles on loan connected with the history of the county. It is hoped that her Grace the Duchess of Sutherland will open the exhibition. Lectures to be delivered during the exhibition by well-known masters of arts and crafts are being arranged.

How to Adopt the Metric System.—Great Britain must adopt the metric system for the same reasons that enforce the adoption of any

other improvements. We must progress, or be content to fall out of the race and become derelict. The change is necessary, because our systems for weighing and measuring were badly conceived; they do not compare in efficiency with the metric system. But in carefully analysing the metric system under practical use, it is clear that, although the system has stood the test of use satisfactorily, the operative units in use with it are not satisfactory. Improvement is called for. The people who have adopted the metric system with the metre units have installed units that are condemned. All the English-speaking people are using systems of weights and measures which are based on the inch units. The adoption of the metric system in place of our present systems could be accomplished with very slight trouble or cost; the great cost and obstruction is due to the entire changing of our inch units. Uniformity of systems and units for measurements is very desirable, if practicable, and there are two methods by which uniformity may be obtained. Firstly, the English-speaking people can adopt the metric system and enforce the metre units, and cast away all their inch units, weights, and measures, and make the necessary sacrifice in commerce and in their institutions. That would obtain uniformity, with the perpetuation of the present imperfect units derived from the metre. Another way to uniformity is for the English people to adopt the metric system and use it with their own present inch units. This would secure uniformity of systems throughout the 1,000,000,000 people and uniformity of units with the 550,000,000 now using the inch units. The 450,000,000 people now using the metre units would be forced to use the inch units by their perfection, whilst England would be saved this terrific and useless sacrifice. This power is reserved in our inch length unit.—Mr. Thomas Parker, in "The World's Work" for February.

LORD RAYLEIGH on Shadows.—The first Friday evening meeting of the present season was held at the Royal Institution on Friday last week, when Lord Rayleigh gave a lecture on "Shadows." He first showed that, as was predicted by Poisson from theoretical considerations, in the centre of the optical shadows cast by a small circular disc, just where the shadow might be expected to be darkest, there was a bright spot. He then showed that this bright spot could be imitated with an acoustic shadow, and he demonstrated that a sensitive flame was affected and made to flare by a source of sound, such as a bird call, even when a circular sheet of glass was interposed between them, always provided that the flame, the bird call, and the centre of the glass disc were exactly in the same straight line. He then went on to prove experimentally that the same thing happened with a sphere, a result which he had also succeeded in arriving at mathematically. In connection with this he referred to Marconi's results in signalling across the Atlantic, and said that the explanation of the feat was obscure, because from what we knew of shadows we should have expected that the waves would have passed only with difficulty round such an obstacle as was constituted by the sea, which rose something like a hundred miles above the straight line between the two points on each side. But if it was difficult for a wave, whether of sound or light, to pass round a convex surface, conversely it passed round a concave surface with extra facility, as, for instance, in the Whispering Gallery at St. Paul's, where it seemed as if the sound clung to the circumference. This phenomenon he illustrated experimentally with a miniature gallery, and, placing the bird-call so that its sound was sent tangentially into the gallery and arranging the sensitive flame at the opposite end of the diameter, he showed that the effect of the sound on the flame was diminished, if not completely stopped, by holding a narrow strip of wood vertically against the side of the gallery at any point. Finally, he referred to the problem of binaural hearing. The two ears gave us information, in particular as to the direction whence a sound came, which could not be obtained with one alone, but it was difficult to explain why. The most obvious explanation was that the nearer ear heard most clearly, but that could not be maintained as sufficient, since people who heard with only one ear sometimes showed considerable power of locating sound. Still there was no other explanation available. He commended this problem to his audience as one on which they might experiment, warning them, however, that though such experiments would require very little, if any, apparatus, they must be conducted in the open air, to avoid the disturbing effects of reflection of sound from walls, ceilings, etc.

THE BRECHIN EXHIBITION.

To the Editors

Gentlemen,—May I, on behalf of the Brechin Exhibition Committee, be allowed to express through your columns our extreme regret and annoyance on learning that a number of the recipients of our prospectus had been surcharged by the postal authorities on account of the packet containing a circular in type-writing characters. To those of your readers who have been annoyed by the exaction, may we urge that in this matter we are more deserving of sympathy than of censure, the trouble being entirely due to the neglect of the postal officials here, who, through ignorance of their own regulations, failed to impress the packets with the special stamp required.

Trusting this explanation may to some extent prevent the sins of an absurd Department from being visited on our heads, and thanking you in anticipation,—I am, Gentlemen, yours sincerely,

J. KIRK, Joint Hon. Sec.

Brechin, January 23, 1904.

RADIO-ACTIVITY.

To the Editors.

Gentlemen,—I notice in your article on "Radio-Activity," in your issue of January 15, that you refer in detail to some work I did six years ago. One important point, however, you have failed to mention, i.e., that all the emanations I was then dealing with will not pass through glass. This seems to separate them from what is now spoken of as radio-activity.—Yours, etc.,

W. J. RUSSELL.

Davy-Faraday Laboratory,
January 22, 1904.

REMOVING GREEN FOG FROM NEGATIVES.

To the Editors.

Gentlemen,—In reference to your article of the 15th inst. on the pyro-soda developer, in which you mention that the pyro-ammonia developer is more prone to give green fog, and recommend a very dilute solution of Howard-Farmer's reducer being rubbed on the wet negative with a pledget of cotton-wool, I know the plan is efficacious; but another simple method of attaining the same end is to allow the negative to dry as usual, and then with a piece of swansdown or flannellette placed over the finger and moistened with methylated spirit lightly rub the fog off, as it is simply a surface deposit, and yields readily to this treatment. Some of your readers may be glad to know this method.—Yours faithfully,

W. GUTTENBERG.

35, Brondesbury Villas, Kilburn,
January 21, 1904.

OVER-PRODUCTIVENESS IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—My name having been mentioned by Mr. Herbert Spackman in his reply to Mr. Lockett's article, "Over-Productiveness in Photography," I, too, would like to join Mr. Spackman in his advice not to have a general smash up of old negatives. Let them lie, and although they will be the same a year or two hence, the ideas of the worker who is at all sincere will be very different, and going through them again he will regard them from a different and more advanced standpoint, and realise in them many possibilities which had escaped his narrower perception of the past. A negative is merely a way to an end, but not necessarily to one end only.

It is like a bridge over which one has to pass to cross the stream, but once over the paths extend in every direction.

The revival of gum has immensely widened the path of pictorial possibility, and in this process many of the old negatives should enter upon a new lease of life, for this method, which *is*, and *must be* the medium for pictorial expression, will get more art out of negative—paradoxical as it may seem—than it ever contained. Thus with greater power of both hand and head, the conception is enlarging, and the outlook widening, and so the possibilities of a negative are proportionately increasing. It may be sometimes advisable to stop actual working for a period, but the head should be kept going all the while, and on the resumption of mechanical activity it will be found in the results that such time has not been lost. Not only would I say save the negatives, but save also the old pictorial failures, which, as object-lessons, will teach far more forcibly than the so-called successes. Failure spurs one on, and all that is best within one responds to the call, realising that the greater the difficulty, the greater will be the triumph.—Yours, etc.,

J. PAGE CROFT.

Quadrant Chambers, Birmingham,
January 22, 1904.

To the Editors.

Gentlemen,—I must plead guilty to a feeling of sinful amusement on reading Mr. Herbert Spackman's criticism of my recent article. It is such a brilliantly perverse example of misinterpretation. To begin with, he accuses me of "endeavouring to draw comparisons between the work of the artist and that of the photographer, to the detriment of the latter." I rubbed my eyes on reading this, and began to wonder "if wisions were about." Considering that I had written with a directly opposite intention, such an accusation seemed at least unkind!

So I turned to the impugned article and read it carefully over, in some trepidation lest that hereditary foe of writers, the printer, had introduced something "not in the wording of the bond." But no; my very first paragraph contained a strong argument in favour of the equality of photographer and artist.

My esteemed critic (I hope he will forgive me if this reply is not in every respect as amiable as I have tried to make it) says I leave the misleading impression that photographers are all of the "touch the button" class, and unworthy to hold a candle to such men as Millais or Leighton. Where, oh where, must be my plaintive question, have I used words which, by the wildest stretch of imagination, can be forced to assume such a meaning?

Then Mr. Spackman, falling foul of my suggestion that on the completion of a photographic masterpiece the producer thereof would be wise to smash the negative, in order to preserve the uniqueness and enhance the value of his work, says, "there is no more need for the successful pictorial photographer to break his negatives after the first production, than there is for the first-class artists on canvas to break their brushes and easels." Quite so, I admit it; but is not the comparison a little mixed? I did not suggest that, say, Messrs. Horsley Hinton, or Craig Amman should smash their cameras and burn their tripods; it was the "idolatry of the negative" against which my words were directed—quite a different matter. Why is gold more precious than silver, radium more valuable than ether? In a precisely similar manner a photographic masterpiece would gain in value and estimation if it were known to be the only copy in existence. This was the reasoning which formed the underlying motive of my article—a plea to the artist of the camera not to "make himself too cheap," by taking undue advantage of his facilities of reproduction. Let him have copies, as many as he pleases, but from the picture itself, not the original negative. We can buy an etching or chromo-lithograph of a famous painting, but can we order duplicates by the score from the artist?

Finally, Mr. Spackman says, "it is a great mistake to assume that extra copies of any particular success in pictorial photography can be turned out in a mechanical manner, merely because the worker may possess the negative." I should think so, indeed—a mistake I am never in any danger of making. It is precisely the fact, that no

points obtained from the same negative, if controlled and manipulated from the same negative, if controlled and manipulated forms one of the strongest arguments against duplication.

There is at least one prominent studio owner in the States, who has adopted the principle of "one negative, one print," with conspicuous success. And if it can be done by the professional, surely the art-loving amateur should be ashamed of throwing his works about in wholesale and promiscuous style now, alas, so common.—I am, Gentlemen, yours truly,

A. LOCKETT.

COLOUR PHOTOGRAPHY.

To the Editors.

Gentlemen,—At the meeting of the Camera Club last week, when Cooper-Hewitt mercury lamp was demonstrated, a very interesting fact was discovered by myself, which I think is worth putting on record, as it may be of value to workers in colour photography. The fact was that certain dyeing materials used in the construction of colour filters have the property of changing the wave lengths of light. This was observed in making the following experiment. Being anxious of testing the value of the light for colour photography, I made some exposures through a red screen which absolutely absorbed all the blue light; to my surprise, with ten seconds' exposure, exposure plates resulted. On examining the light, which, as is well known, gives practically no light in the red portion of the spectrum, through the screen with a spectroscope, it was found that a broad band of red became visible. An inquiry into this matter led me to the opinion that it was due to the screen, composed of red, stained gelatine, becoming fluorescent, but this is a matter of opinion. The undoubted fact remained that red light was produced direct from blue, or perhaps yellow, owing to change of wave length. It was also found that the interposition of other red dyes produced the same results. If this result is obtained with Cooper-Hewitt light, it is probable that other light, such as light from arc lamps, produces the same effects, and would not for the possibility of obtaining photographic images through colour filters by light which is primarily deficient in the recorded spectrum, which will account for some of the anomalies met with in colour work.—I am, Sirs, yours faithfully,

ERNST GRUN.

1, The Hall, Southwick, Brighton.
January 21, 1904.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen,—Messrs. Newton and Bull's answer to my letter in the last issue of your esteemed journal contains the following statement: "With arc light reflected from white blotting paper the ratio of A and C is as 5 to 9." Now this practically confirms my ratio of 1 to 2, and further corresponds with my tests made with descendent gas light exactly as I anticipated.

I say at the same time that: "We entirely adhere to every statement made in our paper" (which, I may repeat, was to the effect that descendent gas light is used the ratio becomes 21 to 480) forbids any discussion.

But although the lecturers adhere to their first statement, they make a second one, and as the conditions of the latter correspond to those of the practical worker, I am fully satisfied, but it will be difficult to understand why the experimenters made use of a source of light, which, according to the above two statements, furnishes results so widely different to those obtained with electric light, and at the same time speed numbers which can therefore be of no practical value. I also say that they refuse to be drawn into a discussion which, I suggest, I opened for advertising purposes. That is, to say the least of it, a very bold insinuation. My letter was that of an entirely independent worker, who has no more interest in the matter than any other person who made isochromatic photography for occupation for the last twelve years.

I further suggest that I am probably responsible for the inser-

tion of an expensive full-page advertisement to open a technical quarrel means to over-estimate the value of Messrs. Newton and Bull's lecture, in face of Professor Valenta's publications during the last three years, and to point to my attempt to reproduce the spectrum by photo-mechanical means, which resulted in failure, not due to my, but the printer's and etcher's incompetence, invites my remark, that it is very careless to indulge in the pleasure of throwing stones whilst sitting in a glasshouse. The lecturers' trichromatic representation of the spectrum in the PHOTOGRAPHIC JOURNAL is still in my mind.

They further honour my trichromatic filters with a reference, and state that their own are more correct, but also, that their red sensation negative requires six times as much exposure as the green sensation. Professor Dr. Eder gives the ratio of correct filters for the above emulsions as 1 to 1, and my ratio is 1 to 1½ or 2, whereas the lecturers' ratio is 1 to 6.

A careful study of Dr. Eder's "Spectral Analytic Studies," a paper read before the Academy of Science in Vienna may induce Mr. Newton to offer his students more satisfactory trichromatic working methods.

The rest of the letter is of a personal character, which I very much regret, but need not answer.

Thanking you for the insertion of this letter,—I am, Gentlemen, yours obediently,

HENRY O. KLEIN.

9, Upper Brighton Terrace, Surbiton, S.W.

Answers to Correspondents.

**** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**

**** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**

**** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**

**** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

London Photographic Company, Limited, 12, Baker Street, London, W. *Photograph of C. Cook.*

C. de Valroché, 154, Queen's Road, Liverpool. *Photograph of the Sisters Sprague in their Flying Act.*

A. J. Waggett, 18, Bedford Place, Brighton. *Photograph of a Specimen of Wood Carving.*

W. J. Wright, Grosvenor Studio, Church Road, Upper Norwood, London. *Photograph of a Photographic Accessory.*

J. C. H. Balmain, 69, Shandwick Place, Edinburgh. *Photograph of "Cinderella" at her Couch in the Pantomime, the Royal Edinburgh. Photograph of Little Florrie Dixon in "Cinderella." Photograph of Group of Comedians, etc., in "Cinderella."*

J. Drinkwater, 11, Station Road, Altrincham. *Photograph of a Rural Scene showing a Sheep and Lamb Pasturing.*

F. Methold, Thorne Court, Shrimpling, Suffolk. *Photograph of a recently discovered Portrait of Shakespeare.*

W. AIMER.—A letter in the local press should meet the case.

HAROLD LEWIS.—If there was no name on the print it was destroyed when your query was answered in October.

RETOUCHING.—"R. P." says: "I enclose a few specimens of retouching. Kindly give me your opinion of them." In reply: The work is fairly good, but considerably overdone.

THE DAGUERRETYPE PROCESS.—C. W. COE writes as follows: "If 'A. Axlade,' whom you replied to last week, would communicate with me he can see a direction of how to work Daguerre-type, and cuts of the apparatus." Mr. Coe's address is 52, Queen Victoria Street, E.C.

CARBON TISSUE.—"BICHROMATE" says: "I should esteem it a great favour if you could give me a formula for making carbon tissue, or direct me to where I could find same, as I am desirous of experimenting in this direction." In reply: Mr. E. J. Wall, in his work on "Carbon Printing," gives formulæ for making the tissue. You cannot do better than refer to this book.

PROCESS BLOCKS.—R. MEREDITH writes: "I am anxious to learn how to make printer's blocks—viz., zinc, half-tone, copper half-tone, and line work, etc. Kindly inform me what book or books to commence with." In reply: "Half-tone Process on Zinc and Copper," by Verlasser; and "Half-tone Process on the American Basis," by W. Cronenberg. The books may be had through any of the dealers or booksellers. We do not supply them.

LANTERN SLIDE TRANSFERS.—P. ROBINSON says: "I would be much obliged if you would tell me the name and address of any firms where I could procure transfers for making coloured magic lantern slides." In reply: We presume they may be had through any of the dealers who supply lantern requisites. Write to Mr. W. C. Hughes, 82, Mortimer Road, Kingsland, N. He may possibly supply you.

DARK SLIDES.—"SLIDES" asks: "Will you kindly give me your advice on the following? It is necessary for me to carry a 1-1 plate camera along with 12 plates. The ordinary wooden slides are too heavy to carry any distance, besides being very bulky. Can you recommend the metal or cardboard ones advertised?" In reply: Both the metal and cardboard slides are used, and they answer the purpose. But we prefer the wood ones ourselves, but of course they are more weighty than the others.

REMOVING FILM FROM PRINT.—"FILM" (Liverpool) writes: "Would you kindly let me know if there is any method of separating the gelatine film from the backing on P.O.P. (after exposure, etc.) without damaging or tearing the film?" In reply: The only method we can suggest is to harden the film with alum, or formaline, and then moisten the back of the paper with water and rub it off with the finger. With care and patience the paper can be removed in this way.

ENLARGING.—"AMATEUR IN EARNEST" says: "In reply to the answer given to my query in last week's Journal, I did not send the focus of my lens. I want to make an enlarger from a cabinet to 15in. by 12in., but cannot clearly work it out for this focus lens by the "Almanac" table." In reply: There is nothing to work out. If you will refer to the table it shows at a glance the distance the lens must be from the negative and from the sensitive plate.

LENS QUERY.—"NEMO" says: "The accompanying negative was taken with a lens of high quality, working at F. 6.3, and used at full aperture. The distance between the lens and the newspaper was about 2 yards, and the focussing was done carefully. I do not think the result is so sharp as it ought to be, and should much like to have your opinion. I made several exposures with a similar result." In reply: The negative is so much over-exposed and the grain of the plate so coarse that we are unable to express any opinion as to the quality of the lens with which it was taken.

CARBON TISSUE.—"BEDFORD CIRCUIT" says: "I think that it would be a very great convenience to those photographers who keep a stock of the various coloured carbon tissues (non-sensitive), if you could induce the makers to affix a small legibly printed label on the inside corner end of the roll, with the name of the colour clearly printed thus. This could be read quite easily by looking inside the end, and would be there as long as any tissue was." In reply: We were under the impression that the makers of carbon tissue always attached a label, or marked the ends of the band with the name of the colour.

PICTURE POST-CARDS.—"F. K." asks: "Can you give me any information to questions below? (1) Are there any manufacturers of P.O.P. post-cards in Germany? If so, kindly state name and address? (2) Please state if any firms publish photo pictorial post-cards in Germany as in this country? (3) If they do not manufacture P.O.P. post-cards in Germany at present can you give name and address of any German firm that would undertake

to make for me?" In reply: As picture post-cards are such a large industry in Germany we assume that P.O.P. post-cards supplied there, but we cannot say who are the makers of them. The cards are supplied by nearly all the P.O.P. makers here, there is no necessity to get them "made in Germany."

COPYRIGHT QUERY.—"A. C." says: "A customer has brought an engraving, 1810, to be reproduced as a line block, and enquired information on which shall be copyrighted to obtain protection for both? (a) The photographic print; (b) the impression from the line block; (c) is it necessary to copyright both, and if so, fee on (b)? The engraving will be improved, and so will negative, so that it will be easy to discover should anyone copy our reproduction, and we are aware that anyone else reproduce the same engraving if they have a second copy." In reply: If a print from the worked-up negative be made correct it will cover that in the block. The fee for registration at Stationers' Hall is 1s.

STAINED PRINT.—"BOVINE" writes: "I enclose a print taken on Velox special portrait paper, and should be glad if you would let me know the reason of the dirty whites and general fog over the entire print. Negative: Dense, somewhat fogged, good detail resulting in a splendid silver print. Exposure: 2½ minutes, 18in. from Duplex wall lamp, fitted with reflector. Development: Result alike in both instances, although actual print sent with oxalate, M.Q. developer or ferrous oxalate." In reply: The makers do not recommend the ferrous oxalate developer Velox, although it can be used. The "M. Q." is what is recommended with pure sulphite of soda; this is important. Probably the sulphite you used was inferior; if so, that would account for the trouble.

BOOKS WANTED.—"J. N." asks: "Will you kindly answer the following questions? (1) The best book or set of articles in English on emulsion making. (2) The date of the best set of articles (same subject) which have appeared in either the Journal or "Almanac." (3) Best chemicals to remove silver stains from fingers. (4) Best English text book on "Photographic Chemistry." In reply: (1) Abney's "Photography with Emulsion." (2) Many articles on the subject appeared in the Journal twenty or so years ago, but not recently; Abney's book gives every information. (3) Cyanide of potassium is what was almost universally used by the old wet plate workers, but it must be used if there are any cuts or abrasions on the fingers, as it is very poisonous. (4) "Chemistry for Photographers," by Townsend, or Meldola's book on the same subject.

* * Several articles—including one on the barium salts as "eliminators"—notices of apparatus, reviews of books, and answers to correspondents are unavoidably held over. These will appear next week's JOURNAL.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received only on the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography

The Oldest Photographic Journal in the World.

ESTABLISHED 1854.

EX CATHEDRA.

Convention. At the Council Meeting of the Photographic Convention of the United Kingdom, held on the 28th ult., a communication was read from Sir William Abney, expressing great regret that, owing to his medical adviser insisting on his spending July in the South of France, it would be impossible for him to be present at the Convention Meeting to be held this year in Derby. The Council at once proceeded to elect another President, the choice unanimously falling on Mr. Alderman H. Strutt, who is President of the Derby Photographic Society, and Sheriff of the County. The local Committees were hard at work, and the proposed programme for the week should prove most enjoyable. The entire ground for the meeting, including the Albert Hall (where the Concessions and Exhibition of Pictures and Apparatus will be held). This is one of the finest rooms in Derby, and will seat 500 comfortably. The date of the meeting is from the 11th to 16th inclusive.

* * *

Diaphragm. A difficulty has always been felt in using the iris diaphragm with convertible lenses. If we have three lenses of different foci and a mount for their common use, either singly or in combination as doublets, provision must be made for indicating six sets of apertures, according to the six available foci. The

moveable ring with separately-engraved scales presents certain advantages in comparison with the Zeiss system, which depends upon an engraved millimetre scale upon the mount; but Messrs. Hordry and Durand offer another solution of the difficulty, which appears to be a step nearer to a perfect system. The lens tube is engraved with a series of curved lines in a longitudinal direction, spreading out in a fan-like order. If we imagine six circles drawn round the tube, parallel to each other, at definite distances, the longitudinal lines will be cut at six different points. Each longitudinal line is used for one relative aperture for the six different foci, and the points at which the six rings intersect, indicate the position at which the index should be placed to open or close the diaphragm for a given aperture. The index is a loose tube, with a diagonal slot, which may be revolved upon the lens tube. At distances corresponding to our six imaginary rings, a short line is engraved at the edge of the diagonal slot. Against each of these short lines the focal length, to which it is assigned, is engraved. As the loose tube is revolved, any one of the short lines may be made to intersect the horizontal lines in succession. The loose tube actuates the iris diaphragm and thus the lens is stopped down to the desired aperture. If well made, this arrangement should be as simple to use as the ordinary iris diaphragm. An illustration of it may be seen in the "Photo Gazette."

Explosion of Gas Cylinder.

Last week we mentioned in a brief paragraph an accident with a cylinder containing hydrogen, by which a person unfortunately lost his life. This accident should serve as a warning to all users of compressed gas. The facts seem to be that the man placed the cylinder close to a wood fire, and after a time it exploded and so injured him that he died in the Greenwich Hospital, to which he was taken. At the present time gas cylinders are carefully tested before use and when they are filled, although to a tremendous pressure, there is always a good margin for safety. Now, all gases expand with heat, when, of course, the pressure within the cylinder is considerably increased, and if the cylinder becomes greatly heated the margin of safety may be passed, and an explosion brought about by the sheer pressure within as was no doubt the case in this instance. Why we specially call attention to this matter is that we have more than once seen fully-charged cylinders of oxygen when in use placed very close to stoves giving off a considerable amount of heat, which, naturally, materially increases the pressure within the cylinder. For this reason we would advise all users of compressed gases to avoid placing the cylinders anywhere where they are likely to become heated, or even warmed to any material degree. Not so very long ago a fire

occurred in a building in which there was one or more cylinders filled with oxygen, and one of those exploded with terrific force, blowing out the walls and doing considerable damage beyond what the fire itself would have done.

* * *

Valentines. The feast of St. Valentine, which falls upon the 14th instant, was, until quite recent times, looked forward to by many persons as quite an important date. Possibly the Christmas and Easter cards have, to a large extent, taken the place of those highly-ornamental missives which used to be quite a heavy burden to the postman. In 1870, more than a million and a half valentines were carried through the post in England alone, which would give one for every thirteen of the population at that date. It would be interesting to know how far the old custom is now kept up, and to what extent the more modern Christmas and New Year's cards have extinguished it, to say nothing of photographic post-cards. Possibly some enterprising trader will once more try to revive the glories of St. Valentine's Day by the introduction of a new form of missive in which photography will take a leading part. The old valentines were of two kinds, the harmless and amorous, and the vulgar and abusive. The first very often depicted a lady and gentleman talking at a stile, while near at hand was a village church, in case it might occur to them to be married. The other kind of valentine generally consisted of a villainously drawn caricature, with some scurrilous abuse attached, which formed a convenient method of insulting an acquaintance without much fear of being found out. The original St. Valentine, we believe, was a good bishop who suffered martyrdom in the second century, but why his name should be linked to these inane or uncouth productions we have not the least idea, unless it be that the recipients thereof may be regarded in the light of martyrs as well. We recently saw in a suburban shop a number of caricature valentines for sale, so that the custom is not quite dead. If such things could be replaced by pretty photographs, the memory of St. Valentine would be kept green in a more decorous and pleasant manner.

* * *

A Comparison of Orthochromatic Plates. In the October number of the "Photographic Journal" a paper was published under this title, the authors being Messrs. A. J. Newton and A. J. Bull. The title must be regarded as an unfortunate one, as it does not denote all the plates brought into comparison, some being included, which are looked upon as belonging to the ordinary or pseudochromatic class. As the comparative exposures were made by the light of a Welsbach incandescent gas burner, which is distinctly yellower than daylight, the results favour the orthochromatic plates in a marked degree. We could point to two plates by the same firm, the speed of which is given by the makers as 1 to 8, but which in these experiments give 1 to 6.3. The slower of the two is an orthochromatic plate, and the more rapid, an ordinary one, is considerably prejudiced by the comparison. We draw attention to the fact, because those who have not studied the subject, might readily infer that the comparative exposures are an index to the sensitiveness of the plates under ordinary conditions of daylight. Although Messrs. Newton and Bull made the necessary reservations, such material is very tempting to those who may have an axe to grind. This is precisely what has happened. The second January issue of the "Photographische Mitteilungen" contains a paragraph giving some of the results of Messrs. Newton and Bull's experi-

ments. The speed list is published without any indication to separate the ordinary from the orthochromatic plates which might have been done for the guidance of the foreign reader; and a German orthochromatic plate has been placed at the head. In the list given by Messrs. Newton and Bull, an English plate, sensitised by dipping, shows to considerably greater advantage, but for some obscure reason it has been omitted. It is in this way that evidence is prepared abroad for the unwary, and we think it our duty to the photographer to publish a warning against such practices.

* * *

Tell-tale Finger-marks. We have recently had the opportunity of learning something more concerning the manner in which the finger-print which led to the discovery of the Conduit Street burglars was photographed, and how that picture led to the identification of one of the delinquents. Burglars are often described as "cool hands," but this term does not imply that their digital extremities are actually at a low temperature. Indeed, we may assume that the work involved to one unaccustomed to labour, must generally afford a example of energy converted into heat. In the Conduit Street case, the incriminating finger-mark, to put the matter in a vulgar tongue, was a sweat-mark, left on a corrugated glass of a skylight. It required abnormal sharpness of eye to detect it, and some knowledge of photography to picture it, and the officials at New Scotland Yard must be congratulated upon both achievements. It is by no means an easy thing to photograph such a mark upon a transparent surface, but the picture, which we have seen, is an excellent one, showing all the delicate surface ridges of the skin. It was procured by throwing a strong side-light on the finger-print, while the glass was placed above a black background. But this was only a preliminary part of the work, it remained to search the finger-print records to find one, out of more than a million which agreed with this particular picture. The search occupied several expert hands for three days, and at length the wanted image turned up. If the burglar had only been considerate enough to have left impressions of his finger-tips of both hands behind him the search would have been complete in about three minutes. The system of classification of finger-prints is most marvellously complete, but quick identification depends upon records in which all the finger- and thumb-marks of an individual are available. Every prisoner who passes through the hands of the police adds his mark to the collection, so that every day it becomes more valuable for identification purposes.

* * *

Cyanide Poisoning. The tragic sequel to the conviction of the late Whitaker Wright once more brings into prominence the deadly poisonous nature of cyanide of potassium. Whitaker Wright was not the first to swallow this deadly salt to escape from justice. It will be remembered that the man Sarti, who was a few years ago concerned in receiving some stolen ingots of silver, managed, while about to be arrested, to drink a solution of the salt with fatal result. At the present time cyanide of potassium has but a limited use in photography, except with those who employ the wet collodion process, as for negatives for process blocks and for carbon or platinotype, enlargements. At the time when the wet process was the only one in vogue cyanide was the almost universal fixing agent, and was to be found in every dark room. Then deaths from it were much more frequent than at the present time—either from accidental design. Solutions of it were frequently left in ves-

ilar to those from which water or other beverage was occasionally drunk, and in the subdued light of the dark room the one was sometimes mistaken for the other, and with fatal result, often within four or five minutes. In the case of Whitaker Wright, according to the medical experts' opinion, some fifteen minutes elapsed between taking the poison and death. This seems a long time, compared with some previously recorded cases. That is probably accounted for by the fact that Wright had not long before eaten lunch, and the stomach was fairly full, also that cyanide was taken in the solid form, and it would take some time to dissolve and become diffused. Unfortunately cyanide of potassium there is no known official antidote, as there is with another deadly poison used in photography—bichloride of mercury. The action of this is slower than that of the cyanide of potassium, and if, after solution of it be swallowed, the whites of one or two eyes be quickly administered no harm will result. The mercuric iodine forms an insoluble compound with the mercuric iodide, which is practically harmless. The best suggested antidote in the case of cyanide of potassium is a solution of sulphate of iron; it, with the cyanide, forms prussiate of iron—Prussian blue—which is an insoluble compound and inert. But it must be administered at once, and before the cyanide has become diffused through the system. We mention this, in case of accident, sulphate of iron is usually at hand, and life may possibly be saved, but not a moment should be lost in administering the antidote.

* * *

The Metric System.

A petition promoted by the Decimal Association is being extensively circulated throughout the United Kingdom in support of the proposed adoption of the metric weights and measures, which will be introduced in the House of Lords by Lord Haversham, and will be seconded by Lord Kelvin. The metric system has already been legalised in this country, and sooner or later, it is bound to become of universal application, but it will only be under compulsion. Our old clumsy system will endure until its abolition is made compulsory by Act of Parliament, as it would be impossible for the two systems to run contemporaneously. The old system will no doubt die hard, for it will not be easy to convince, say, our retail shopkeepers and those who draw their household supplies from them, that the metric system of weights and measures is better than our present one of pounds, yards, quarts, and gallons. England is the only country in Europe where the metric system does not exist, and only those who have travelled on the Continent can realise how simple and convenient it is as compared with our present system. At present all the photographic plates we get from the Continent, of course, come to be written under the metric system, and when translated into our weights and measures often suffer, particularly where small quantities are concerned. Though our "Almanack" has for years past given a table of the equivalents of grammes and ounces and metres and inches, and the method of converting the one system into the other, the matter does not seem to be thoroughly understood by some. Our old friend, the late Mr. J. Traillor, once wrote that the simplest way to convert the scale into the Fahrenheit scale was to have a shilling thermometer graduated with both scales and a glance would show the equivalents. Glass measures are to be graduated with the metric scale on one side and pints and ounces on the other, so that the same measure would answer under the two systems. We have a set of some weights weighing up to three hundred grammes each weight of which, with figure punches, we have had their equivalents in English grains so that both

our weights and measures are serviceable under either system. Most photographers after perhaps the first, will hail with satisfaction the universal adoption of the metric system of weights and measures.

* * *

"A New Force."

A few weeks ago we remarked upon the extraordinary inventive genius of a man with an unpronounceable name, and ventured to remark that the only redeeming feature of his work was the money it must have brought to the Patent Office in the shape of fees. There must be quite a number of men of this type about, and the curious part of the business is that the greater their pretensions the more the newspapers present them with "bold" and free advertisements. As an example of this kind of thing we may refer to a notice which appeared quite recently in the "New York Tribune," which tells how a gentleman of the name of Steele has discovered a new form of force which he has modestly named "Steelecity." If what half we are told about it is true it will come as a boon and blessing to men and especially photographers, for it will furnish them with light, heat, and power at very slight cost. This is what the inventor says about it: "This new force is taken from the most simple elements of nature, and, utilised in connection with special mechanical devices, is capable of producing light, heat, and power, jointly or separately." With a plant of insignificant initial cost, he declares that a light of 158 candle power, similar in quality to the sun's rays, can be produced and maintained at a cost of one-fourth that of running a sixteen candle power incandescent electric light. Moreover, he points out that this same plant will heat a building, run the elevator, and do the cooking, without odour, dirt, or expert attention. After reading this glowing account of "the new force," and after one has recovered the shock of that perusal, it will dawn upon the mind that at last Radium must take a back seat. For Radium is unattainable except by millionaires, and they do not possess so much as an ounce of it between them. But here we have a something—we are not told whether it is a solid, a liquid, or a gas—that will do for us much more than Radium ever promised, and it costs next to nothing. In the account from which we have quoted names of prominent men are freely given, we are told that money has been fully subscribed to the "Steelecity Corporation," and that this Corporation will "cheapen every feature of light, heat, and transportation to owners, users, and consumers." We shall await with much interest further particulars concerning this remarkable discovery, for at present we are told only what it will do. We naturally are curious to know what it is. There is a grandeur and breadth about the American reports of a new invention or discovery which calls to mind the boasting street boy drawn by the late Phil May:—

"My father, 'E once caught a fish as big—as our street!"

"Well, then, it must 'ave bin a whale."

"Garn, 'E were baitin' wi' whales!"

* * *

Vandalism.

Photographers, together with others of artistic aspirations, will join in the cry which is going up continually against the destruction of natural scenery. There are two notable places which are just now in peril, one being the grand gorge through the limestone cliffs at Cheddar, and the other the famous rock-bound and wooded heights of the Avon at Clifton, near Bristol. To take the Cheddar case first. Anyone who has visited that pretty village, it is hardly a town, will remember the grandeur of those precipitous masses of limestone which form such a beautiful background to it. There is plenty of other limestone in the neighbourhood which "never

would be missed." But it has entered into the mind of certain Vandals that as these cliffs are situated at the top of a road which forms an easy descent towards the railway, it is more remunerative to cut them up into road metal, than it would be to procure that material from other less favoured situations. So the navy, and the steam navy, and other modern engines of destruction are at work doing their best to obliterate a piece of scenery which, so far as this country is concerned, is almost unique. The limestone is pierced in many places with stalactite caves, and we presume that these, if the work be permitted to continue, will perish with the rest. The other view, that at Clifton, is the more famous and better known, and we may suppose that few persons who have visited Bristol have failed to step out of their way in order to see the lovely prospect afforded from the Clifton suspension bridge. The cliffs are precipitous, rising tier upon tier above the water-level for a height of some three hundred feet. Their tops are clothed with verdure, and although the stream below is not a very broad one, it is a highway from the docks to the sea, and many noble ships may sometimes be seen on its surface. The whole forms a most lovely picture, and one might reasonably hope that it would be a permanent one, and a perpetual joy not only to those whose lives are passed in its vicinity, but to all England. But, again, the limestone is wanted for road-mending, and although of that stone there is plenty to be had, the River Avon forms a convenient water-way for its carriage, and the ratepayers will be saved quite a shilling per ton. The utilitarian spirit is so rampant among some of the people who have the control of our municipal cash, although they are prodigal enough sometimes in spending it upon costly fads, that the saving of one shilling will far counter-balance in their minds a loss which cannot be measured in terms of £ s. d. We can only hope that the outcry that is being made by those to whom money is not the sole aim of existence, has not come too late to save these gems of English scenery. Photographers, where they have the opportunity, should not fail to enter their indignant protest against the perpetration of such appalling mischief.

DUST-RECORDS BY PHOTOGRAPHY.

A PAPER read before the Camera Club recently by Colonel Crompton, C.B., calls for something more than the usual notice of such proceedings, for the very good reason that it described a new application of photography. But the above title is altogether our own, the paper read being called, "Dust-Raising Qualities of Motor Cars." It was not a subject that promised interest, either for ourselves or for the majority of our readers, but when we heard at the very beginning of the lecture that a series of most important tests had been made which would have been quite impossible without the aid of the camera, we listened with both ears, and were fully rewarded for our pains.

It seems that a few years ago the Automobile Club offered prizes for vehicles which should come out best under a number of trials as to dust-raising proclivities, and Colonel Crompton and Mr. Crawley were appointed as experts to arrange a system of testing which should be as complete as possible. Their first idea was to arrange by the side of a dusty road a number of trays, and to carefully weigh from time to time the amount of dust deposited therein, similar trays to be carried upon the auto-cars sent in for competition. We may mention, in passing, and in order to show that such a scheme was not Utopian, that similar receptacles have recently been used to catch the dust of Glasgow, and as a result it has been shown that the atmo-

sphere of that city deposits no fewer than sixty-four tons of solid matter per diem.

But, for reasons which we need not enter into, the tray system was abandoned, and records made with the camera, or rather with two cameras operated simultaneously, were adopted instead. Preliminary trials were made upon an ordinary high road, and these gave such hopeful results that it was determined to adopt the photographic method of record-making on a far more extensive scale, and at some place where interruptions from ordinary traffic would not occur. The cycle track at the Crystal Palace was the place ultimately selected, and as the concrete road there is free from dust it became necessary to carpet it with pulverulent material. The most satisfactory stuff for the purpose was found to be the fine sweepings from a flour-mill, and in order that the roadway should present the same condition for every motor car tested, the surface was raked over with fresh material added between each test. A standard car, of stated speeds of which could be relied upon, travelled pilot by the side of every car submitted to trial.

In the first tests made one of the cameras employed was put on an eminence at the side of the track, and the other was placed on the track itself, so as to get both a side view and an end view of each car. But the poor photographer who had to stand on the floury way while the car thundered past at eighteen, twenty-two, and thirty miles an hour protested on his own behalf and that of his camera, and the remaining pictures were taken from two points of view on the windward side of the track.

About five hundred pictures were secured and the typical ones were thrown on the screen as illustrations to Colonel Crompton's remarks. They were not pictorial, but they were extremely interesting. Each showed the same view, a small piece of the cycle track, with raised benches at the back, and above all the tops of a group of poplars. But the dust-cloud which was raised by each vehicle showed many points of difference. In some cases the cloud was of the heavy cumulus kind, keeping close to the ground and quite hiding the wheels of the vehicle; while in another it would be raised like a diaphanous veil, so as to fog much of the picture. In each case a man stood in a prominent position, exhibiting a board upon which was plainly scribbled the number of the car under test at the time. At the same time the judges were careful to make note of the height and general appearance of the dust-cloud raised, as they appeared to the eye. But when afterwards the visual impressions were compared with the actual photographs, it was quite evident that the eye was not to be trusted at all. Certainly the cars in many of the pictures were moving too quickly for good detail to be secured, but a dust-cloud is more leisurely in its onward sweep, and the photographs depicted them most admirably. Doubtless the flour caused a little exaggeration of the clouds, for flour is lighter than ordinary road dust, and hence its light tint was favourable to photographic effect.

It was when the five hundred pictures were printed and sorted that the great value of the method adopted came to be realised. They were first of all arranged in the order of excellence, the least dusty of the cars being placed first, and the rest in order of dustiness, until the last showed cars which were all but obliterated in a fog of their own raising. Then the pictures were catalogued in the same order, and when that was done they were once more mixed up, and again sorted out without reference to the list. It was then proved that the different gradations of the dust clouds were so distinctly shown that the sorters adopted exactly the same order as at first, without reference to a catalogue, with only one or two trifling exceptions. The second time the pictures were purposely thrown into confusion, and again sorted out, with the same satisfactory

result, only two or three changing the places originally assigned to them.

It may be asked, Why were these trials made? The answer is that of all the sins laid to the door of the motor car that of dust-raising is one of the worst. People who reside on such favourite motor car promenades as the Portsmouth road or the Ripley road complain terribly of the dust raised by these highway expresses, and a good deal of the prejudice existing against a system of locomotion which has come to stay would disappear if the dust could be suppressed. The owners of cars are also quite alive to the inconvenience of dust, and have a decided objection to carrying a pound or so of the soil upon their unfortunate persons as the penalty for a short run on a dusty day. And, to do them justice, the cars do not make the dust. The horses' hoofs are mainly responsible for it, although the motor car demonstrates the most effective manner of raising it in clouds. Everyone, indeed, is more or less interested in the question of reducing the amount of floating dust to a minimum, for, apart from its disagreeableness, we all know that it carries with it terms of an undesirable character. The low death-rate of the Kingdom for the past year is attributed to the amount of watering the roads have received from the too constant attentions of Jupiter Pluvius.

It is somewhat beyond our province to deal with the conclusions which have been arrived at from a study of the Sydenham photographs, but as we have many motorists among our readers they will naturally expect us to say something with regard to results. For our part, we may express the hope that the photographs referred to may be publicly exhibited as object-lessons, both to the manufacturers and users of motor cars, for at present everyone is under the firm impression that his own car creates less dust than his neighbour's. The general supposition that the tyre of the vehicle is the chief dust-disturber must be abandoned. It is true that a broad tyre will raise more dust than will a narrow one, and solid and pneumatic tyres behave alike in this respect. There is no difference in dust-raising capacity between a high car or a low car, but there is an immense difference between one which has a clear airway beneath it and one that has not. A car with a silencing-box or any other portion of its paraphernalia hanging down low, so as to leave but a few inches of space between it and the ground, is a terrible dust-raising machine. It offers such an obstruction to the air through which it travels that a mighty wind is thrown out sideways, driving out the dust laterally—and another wind is propelled towards the rear of the car to fill the partial vacuum which it causes.

Such are the general impressions which these experts have gained from the trials, but they will not issue a complete report until further tests have been made. These tests will be concerned with the best form of "body" which a vehicle should have to prevent dust-raising, and different shapes and sizes will be fitted to an approved set of wheels. Both Colonel Crompton and his colleague must be congratulated upon the scientific acumen which they have brought to bear upon these tests, and upon the presence which prompted them to call in the camera to aid them in their labours.

THE British Optical Association.—A lantern lecture will be given by Mr. A. W. Oxbrow, F.R.O.A., F.R.M.S., in the lecture hall of Mount Vernon Hospital, Fitzroy Square, W., on Wednesday, January 17th, at 8 p.m. Members of the Association and also of the enrolment scheme are entitled to bring a friend. The slides shown will give some very interesting and original specimens of highly magnified sections of the human eye. There will also be a short discussion on topics interesting to the sight-testing optician.

PYROGALLIC ACID CRYSTALS.

CRYSTALS of pyrogalllic acid give interesting and varied effects when observed under the microscope either with or without the polarising prism. Pyro readily dissolves in ether, methylated spirits, or water, and with either of these solvents picturesque and striking crystals can be easily prepared. If ether is the solvent, the crystals when viewed by the naked eye present

Fig. I.—Group of Pyro-ether Crystals. Natural Size.

a very effective appearance and bear a resemblance to a group of shells; but, in consequence of the rapid evaporation of ether, pyro-ether crystals are lacking in variety and delicacy.

When the pyro is dissolved in methylated spirit a more varied deposit is formed, providing the crystals are allowed to form in a cool place.

Fig. II. ($\frac{1}{8}$ " Obj.)—Photo-micrograph of Radiating Point of Crystals.

If the pyro is dissolved in water, the crystals are not deposited in such a regular and picturesque formation as when a spirituous solution is used; but, though they are less effective *en masse*, their details offer far more variety in size and structure when viewed under the microscope.

The best effects are obtained when the preparations are

allowed to dry in a cool, damp place. The crystals are prepared by merely pouring a small quantity of pyro solution on a clean piece of glass, the surplus is poured off, and the plate is then placed on end to dry.

The illustration, Fig. I., is a photograph of pyro crystals

Fig. III. ($\frac{3}{8}$ " Obj.).—Photo micrograph of Crystals of Pyro Dissolved in Methylated Spirit.

on a glass plate. The beautiful shell-like formation can be plainly seen in the reproduction. This plate was coated with a solution of pyro in ether.

Fig. II. is a photo-micrograph of the radiating point of the "shells" in Fig. I. It will be noticed that the crystals disperse

Fig. IV. ($\frac{3}{8}$ " Obj.).—Crystals of Pyro Dissolved in Water.

from a common centre, and resemble a bundle of rods. The effect is more striking than artistic.

The next illustration, Fig. III., is a low-power photograph of pyro crystals from a methylated-spirit solution. The photo-

graph was taken from a group of crystals at the extreme of the deposit.

A group of pyro-water crystals is shown in Fig. IV., though the delicacy of the original formation, as viewed through microscope, has been almost lost in the photograph. It will be observed that large, broad crystals are intermingled with feathery deposits in a remarkable manner.

Fig. V. ($\frac{3}{8}$ " Obj.).—Pyro Crystals Photo-micrographed with Polariscope.

The above illustration is a photo-micrograph of crystals from the same plate as Fig. IV., but in this case the photograph was taken with the aid of the polariscope. Pyro with polarized light gives an endless series of colour effects. Unfortunately the rich colouring given by the polarised illumination cannot be reproduced here, although the variety of light and shadow can be partially seen in the illustration.

The water solution of pyro gives by far the best results with the polariser, and really marvellous effects of colouring are seen in all parts of the deposit. Generally speaking, a power such as a $\frac{3}{8}$ in. or 1 in. objective is the best lens for observing pyro crystals, but occasionally an especially delicate deposit of crystals necessitates the use of a higher power.

J. I. PIGG, F.R.P.

IN the Chancery Division of the High Court on January 23rd (Justice Byrne), Mr. Kerly mentioned the case of Kodak, Limited v. City Sale and Exchange Company, which, he said, was an action for an injunction to restrain the defendants from passing off their goods under the name of "Bull's Eye" as the goods of the plaintiff company. Defendants consented to a perpetual injunction, to treat the motion as a trial, and to pay £10 damages and costs as between solicitor and client. His Lordship acquiesced.

COPYRIGHT Protection for Exhibitors at the Louisiana Purchase Exposition.—Both Houses of Congress have passed a law protecting from piracy works of art and literary productions which are exhibited at the St. Louis Exposition, and it is expected and hoped that this proper provision will receive the President's signature. The Bill provides, up to November 30, 1904, for copyright on "intended" for exhibition at St. Louis, on "interim" copyright for two years from such registry, waiving the manufacturer's clause, with proviso that the regular term of copyright shall be from the date of such registry in case an edition of American manufacture is meantime published.

THE **PREMO FILM PACK**

"You put the pack in just as you buy it, and can start right away."—

**Amateur
Photographer.**

THAT IS THE
BEAUTY OF .
THE PREMO .
FILM PACK .

CONTAINS

**TWELVE FLAT
ORTHOCHROMATIC
FILMS IN ONE
SMALL PACK
ALL READY FOR
IMMEDIATE USE IN
ANY GLASS-PLATE
CAMERA.**

For 5/- the Film
Pack Holder can be
made to fit your
Camera without
impairing its use for
Plates.

SOME OF THE ADVANTAGES OF THE FILM PACK.

- The Simplest, quickest, most efficient changing ever devised for flat films.
- Flat films loaded and unloaded in daylight.
- The Lightest, most compact and portable attachment for glass-plate cameras.
- Rapidity in making consecutive exposures.
- Cut films one-fifth the weight of glass.
- Each exposure focussed separately if desired.
- Films and Plates used interchangeably.

NOW is the time to get your Plate-Camera into the best shape for the coming season by means of the DAYLIGHT LOADING PREMO FILM PACK.

The Film Pack Holders or Adapters cost in quarter-plate 4/6 & 5s., and in 5 x 4 6/6; and are readily fitted to any glass-plate camera.

May be obtained from all dealers, or from the distributing agents for the ROCHESTER OPTICAL & CAMERA CO.

KODAK, Ltd., 41-43, CLERKENWELL ROAD, LONDON, E.C.

Wholesale and Retail Branches—96, Bold Street, Liverpool; and 72-74, Buchanan Street, Glasgow.

Retail Branches—59, Brompton Road, S.W.; 60, Cheapside, E.C.; 115, Oxford Street, W.;

171-173, Regent Street, W.; and 40, Strand, London, W.C.

CRISTOID FILMS.

The Ideal Film for the Tropics.

THEY DO NOT CURL THEY CANNOT BE OVER EXPOSED.
THEY ARE THE FASTEST FILMS IN THE WORLD. THEY KEEP PERFECTLY IN ANY CLIMATE.

No trouble to use and are 25 per cent. cheaper than any other Film.

Demonstrations daily at 12.0, 1.15, 3.0, and 5.30 p.m., Saturdays at 12 noon, at Winchester House (Rooms 336 and 337, Lift B), Old Broad Street, E.C.

Obtainable from all Dealers or direct from the Manufacturers. Write for Cristoid Manual, Price Lists, &c.,

SANDELL FILMS & PLATES, Ltd., Norwood Junction, London, S.E.

KINGSTON ENLARGING WORKS,
SOUTHSEA ROAD, KINGSTON-ON-THAMES.

W. KING & CO.'S
ENLARGEMENTS IN BROMIDE, CARBON, & PLATINOTYPE

After being Twelve Years before the Photographic Public,

ARE STILL TO THE FRONT.

TRY OUR SPECIAL LINES, WHICH CONTINUE TO GIVE GREAT SATISFACTION.

We do not employ travellers, our business being chiefly through recommendation; we are therefore enabled to give the full value on all orders entrusted to us.

DEVELOPING, PRINTING, &c., IN ALL STYLES.

WE ARE CERTAIN

HAT many Photographers who do not now use the Aerograph could do so with profit to themselves, and an improvement in their productions.

If you are one of these, and can come to London when purchasing, we are offering a day's instruction in the use of the instrument free, and we are sure that in that short time we can show you enough to make the Aerograph at once useful in your work.

We are also offering to sell the Aerograph on "The Times" Monthly Payment plan; this permits of the

return of the instrument after a month's trial if you do not find it useful in your work, at the cost to you of the first instalment only.

The Aerograph is useful for Carbons, Bromides, Opals, Platinotypes, &c., either cabinet size or enlargements for black and white, sepia or water-colours.

Full particulars on application to—

THE AEROGRAPH COMPANY, LIMITED
30, MEMORIAL HALL BUILDINGS,
FARRINGDON STREET, LONDON, E.C.

A NEW COLLODION EMULSION.

II.

In order to make the collodion emulsion sensitive for yellow and red, ethyl violet (Badische anilin und soda fabrik), first recommended by Valenta, should be used. It is a sensitiser of absolutely ideal quality, for it exerts no prejudicial action on the keeping property nor any other peculiarity of the emulsion, and imparts to it an orange sensitiveness which is at least equal to the sensitiveness to blue. The coloration of the emulsion with ethyl violet also doubles the general sensitiveness, so that a plate thus sensitised is four times as sensitive as a wet collodion plate.

This high colour sensitiveness only appears when the plate coated with the stained emulsion is bathed in water, and it is again for the most part lost when the plate is placed in the developer, which is an extremely valuable property, for a plate so red-sensitive would be extremely difficult to work in the dark room.

Ethyl violet is thus far superior to cyanine, which has previously almost exclusively been used for red sensitising, for the latter is not only uncertain in its action, but gives rise to all sorts of troubles.

Bathing the plate before exposure in a dilute solution of silver nitrate produces no increase of the red sensitiveness, and therefore is not to be recommended.

In order to make the plate sensitive for the yellowish green rays, the eosines should be used. The favourable action of these dyes only appears, as is well known, when a silver salt is used, as eosine, free from silver, is almost without action with ordinary emulsion, and although it acts much better with the new chloro bromide emulsion, it never equals the above described action of ethyl violet.

In sensitising with eosine also, the plate must be bathed before exposure in water, and only then shows a yellowish green sensitiveness, which amounts to about half the blue sensitiveness. It should be noted that commercial eosine is frequently unsuitable for sensitising without free silver; and the chemically pure dye or tetrabromo fluoresceine, which may be easily prepared from the commercial article, should be used.¹ Eosin salts, as already stated, to a very marked degree as a fog preventive, etc.

The eosine plate is specially sensitive for yellow-green, less for the pure green, and not at all for blue-green. When exposed behind a yellow or green filter it reproduces, therefore, blueish-yellow very bright, whilst blueish-green is almost without action, and is too dark.

If an eosine collodion plate is bathed in a 1:1,000 silver nitrate solution, the yellow-green sensitiveness is doubled, and thus about equal to the blue sensitiveness. Dr. Albert's dyes, which consist of silver eosine salts, may, of course, be used, but they possess the above described disadvantage.

Rhodamine may be used in place of eosine; it also gives equally clean, vigorous negatives, and sensitises principally to the yellow rays. The rhodamine emulsion reproduces, therefore, the orange, such as vermillion, relatively bright, but the blueish-green even darker than the eosine sensitising. This dye is, however, worth attention in the reproduction of paintings, and is often preferred to eosine, which reproduces vermillion as black.

Excellent sensitisers are met with in that group of dyes collectively designated as "cyanines." Many of these have been known for some time, but have hardly been prepared; for with the exception of the one dye known as "cyanine" they have had no application.

A short time ago Dr. Miethe prepared a series of other

cyanines, and tested them as to their applicability in photography, and found them of great practical value as sensitisers.

Dr. E. König has entered most fully into the study of the cyanines, and prepared a large number of these dyes, and of these Orthochrom T. has become a favourite sensitiser for gelatine plates.

The ordinary cyanine (lepidin-chinolin-amyl-cyanin) is an energetic red sensitiser; the coloured emulsion, however, will not keep, and the plates fog in development. It is now completely displaced by ethyl violet. A cyanine, introduced by Dr. Miethe under the name of "ethyl red" (chinaldin-chinolin-methyl-ethyl-cyanine) makes silver bromide sensitive for orange, yellow, and green, and increases the general sensitiveness of collodion emulsion to about double that of the undyed film, and at the same time gives no tendency to fog.

Orthochrom T. (p-toluchinaldin-p-toluchinolin-ethyl-cyanine) sensitises in a similar way, but is a dye of a more bluish shade, and therefore its action extends to the reddish-orange. It has proved to be excellent for gelatine plates; in collodion emulsion, however, it tends to the formation of fog, and even with the addition of bromide to the developer a perfectly clean negative can hardly be obtained.

With gelatine plates Orthochrom T. is especially valuable as a red sensitiser, as hitherto a satisfactory sensitiser for these rays has been wanting. It is different, however, with collodion emulsion, for with this ethyl violet is quite unsurpassable; on the other hand, we possess no dye which will give sufficient sensitiveness for pure green and blue-green.

Ethyl red even is not satisfactory in this respect, as its sensitising band only reaches to the blue-green, whilst the particular sensitiveness of the collodio-bromide emulsion only extends to the pure blue.

This hiatus seems now to have been filled up by a purple red cyanine, p-toluchinaldin-chinolin-methyl cyanine, prepared by Dr. E. König. The sensitising action of this dye begins first in the orange, and includes with yellow and green the whole of the blue-green. It gives absolutely clear, vigorous negatives, and is equally as valuable as a green sensitiser as ethyl violet is as a red sensitiser. By the addition of these two dyes in suitable proportions an emulsion is obtained which reproduces with almost equal brightness all pigmentary colours of equal purity and saturation, and without the use of a filter, and which one can therefore designate as approximately "isochromatic."¹ A collodion emulsion thus sensitised is about five times as sensitive as a wet collodion plate.

In conclusion, a few remarks on the use of mixture of the dyes mentioned may be included. As a general rule, a mixture of sensitisers is not to be recommended, and they should be avoided as far as possible. The individual components never hardly exert their full action; the more vigorous sensitiser always predominates, and if equal weights of the dyes are used the action of each is considerably lowered.

For these reasons eosine is not suitable for mixing with ethyl violet. The energetic red sensitiser only allows the eosine to act when the latter is considerably in excess; then, indeed, plates are obtained with equal sensitiveness to red and green, but the former is reduced to a fraction of that which is obtainable by the use of ethyl violet alone. Moreover, some dyes are most unfavourably affected when they chemically react one with another, which is exactly the case with the acid eosine and basic methyl violet.

Dyes of about equal action and similar chemical character may be used together, but a very careful adjustment of the quantities is necessary if they are not to act prejudicially one

¹ A. von Hübl. "Die Kollodiumemulsion," p. 78.

¹ Plates called "panchromatic" are sensitive to all colours, but not equally, so that only by the use of a specially adjusted filter can the above-mentioned result be obtained.

on the other. An important advantage of the new cyanine dyes lies thus in the property they possess of sensitising for an extended colour-range—that is, for a very broad zone of the spectrum, and thus make mixtures of dyes quite unnecessary. They can also be very well combined with ethyl violet, which increases the red sensitiveness.

Substrating the glass with gelatine or indiarubber solution is not necessary; it is quite enough if the edges are roughened or the plate is merely edged with rubber solution. The emulsion should be mixed with the alcoholic solution of the dye and kept in stock, as from the absence of free silver salts it suffers no change.

The following sensitising formulæ can be recommended:—

1. In order to obtain yellow-green sensitive plates 1,000 cc. of emulsion should be mixed with 25 cc. of 1:150 eosine solution, or 15 cc. of 1:150 rhodamine solution.

2. In order to sensitise the emulsion for red 10 cc. of ethyl violet solution 1:500 should be added.

3. An emulsion sensitive to orange, yellow, and green is obtained by adding 44 cc. ethyl red solution 1:500, or 40 cc. of toluchinaldin-cyanine solution 1:500.

4. Finally, if an emulsion is required sensitive to all colours, it should be sensitised with 30 cc. toluchinaldin-cyanine solution 1:500 and 5 cc. ethyl violet solution 1:500.

The plate, after coating with emulsion, must always be washed with water in a dish till the so-called "greasy marks" disappear, or rinsed under a fine rose till the same effect is obtained. During the treatment with water the colour sensitiveness considerably increases, and therefore during this operation, as well as whilst placing the plate in the dark slide, extreme care as to the dark-room light must be observed.

For "orthochromatic" negatives of oil and water-colour paintings, etc., the emulsion may be sensitised with eosine or rhodamine, and the ordinary dark-room illumination is quite satisfactory. If the picture, however, contains much red or brown, ethyl red or the toluchinaldin-cyanine should be chosen, and then in the preparation and development considerable difficulties will be met with. If a fiery purple with saturated yellow are present then the red sensitiveness must be increased with the addition of ethyl violet. In such a case it is advisable, for the sake of safer working, to lower the sensitiveness of the plate by a small addition of bichromate. If bright blue is to be reproduced relatively dark in all cases, a bright yellow filter of picric acid or potassium chromate solution or a dry tartrazine filter should be used.

For three-colour work all the negatives can be taken on the emulsion sensitised according to No. 4 formula through violet, green, and orange filters, or for the yellow-printing negative the unstained emulsion may be used without a filter; for the red-printing negative an eosine emulsion with a yellow filter, or the toluchinaldin-cyanine emulsion with a green filter; for the blue-printing negative the ethyl violet emulsion with an orange filter.

The exposures for these three negatives is about 1 : 2 : 1. The filters should be prepared according to one of the numerous formulæ, and adjusted by trial with a suitable colour-chart.¹

The eosine plate has the advantage that its yellow filter can be very easily prepared. In choosing the same it is only necessary to ensure that the blue of the colour-chart has the necessary density. If, on the other hand, a red sensitive plate is used, these rays must be cut out by the addition of blue or green to the filter, and it is not easy to hit the right thing here.

The plate sensitised with eosine is wanting in, as has already been mentioned, the blue-green sensitiveness, and for this

reason the green in the red-printing negative often appears thin. If the negatives are made with the idea of preparing transparencies this deficiency is of little moment, as one can choose a somewhat fiery blue-green for the blue constituent.

In negatives for trichromatic printing sensitising with toluchinaldin-cyanine, the best of all known sensitisers, green, is to be preferred, for the green formed by the somewhat saddened and slightly greenish Paris blue is so impure that it will hardly stand any more admixture of red.

After exposure the plates should be developed, without preliminary washing, with glycine, and the best form of this is the well-known stock-paste,¹ which should be diluted with 15 parts of water. The addition of bromide, if the temperature of the developer is kept below 18 degrees Centigrade, is not necessary.

Patent News.

The following applications for Patents were made between January 18th and January 23rd, 1904:—

Printing Apparatus.—No. 1,281. "Improvements relating to photographic printing apparatus." William Edwin Hickling.

Printing Frames.—No. 1,282. "Improvements relating to photographic printing frames." William Edwin Hickling.

Apparatus.—No. 1,283. "Improvements in photographic apparatus." Complete specification. George Henry Dorr.

Infinity Catch.—No. 1,425. "A shutter stop and infinity catch facilitating the focussing of photographic cameras." John Barker.

Developing Machines.—No. 1,442. "Improvements in daylight photographic developing machines." George William Lowcock.

FORTHCOMING EXHIBITIONS.

February 10-13.—The Longton and District Photographic Society. Hon. Secretary, T. Mottershead, 43, Stafford Street, Longton, Staffs.

February 13-27.—Scottish National Photographic Salon. Exhibition Secretary, Alex. Mackenzie, 42, Scott Street, Perth.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Secretary, George H. Depledge, 17, Hazeldene Road, Goodman's Field, Essex.

March 5. Last day for entries February 18.—South London Photographic Society. Entry forms from W. Calder Marshall, F.C. 41, Glenton Road, Lee, S.E.

March 5-12.—Brechin Photographic Association. Hon. Secretary, J. Kirk, 1, Infirmary Street, Brechin.

March 8-9.—G.E.R. Mechanics' Institution (photographic section). Hon. secretary, A. Woolford, 16, Grove Green Road, Leytonston.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 25 to April 9.—Northern Photographic Exhibition. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

¹ A. von Hübl. "Die Dreifarbenphotographie," second edition, p. 146. (Messrs. Penrose & Co. are now publishing a translation of this work with chart.—TRANS.)

¹ Hübl's formula is, potassium metabisulphite 14 g., caustic potash 14 g., 80 cc., when dissolved add glycine 10 g. This does not keep quite so well as formula, which is, sodium sulphite 25 g., warm water 40 cc., glycine 10 g., and add potassium carbonate 50 cc., and make total volume up to 150 cc. must be exercised in adding the pot. carb., as strong effervescence ensues. for use with 12 parts water.—TRANS.

New Apparatus, &c.

Albums, etc., for Photographs. Manufactured by Ferd. Anthony Horle and Co., 8, St. John's Lane, E.C.

We have received a catalogue, together with samples of albums and other articles of photographic utility, the manufacture of Ferd.

Anthony Horle and Co. The albums are made to take photographs of all the recognised sizes from very small prints upwards, and may have either to slip in or paste in the photographs. The samples we have before us are very varied in their assortment of shapes, but they

are uniformly tasteful in binding and general get up. There is a wide variety of tints for the leaves, and the various shades seem to have been carefully selected, with due regard to the purpose for which they are intended. The portrait albums have the same good character-

is. A useful contrivance for storing or carrying photographs is a book-form box, having loose leaves which are changeable. Appealing more directly to the professional photographer are translucent envelopes for enclosing prints. These are made for c.d.v.'s, cabinets,

and the usual stock sizes, and are enclosed in various designs or with a pattern upon them in gilt. They are in several delicate tints, and

in style and finish would be fitting accompaniments to the work of a first-rate photographic firm.

The Rystos Electric Lamp for the Dark Room. Manufactured by Reynolds and Branson, Ltd., 14, Commercial Street, Leeds.

To those who have electric current available in their dark rooms we can unhesitatingly commend the Rystos Lamp, both for its convenience and efficiency. The lamp, which measures $8\frac{1}{2}$ inches high by 4 inches wide, has a semi-circular front of ruby glass of a kind which may be relied upon for safety. Within is provided the ordinary incandescent lamp fitting, carrying a lamp hanging downwards. Immediately above this and outside the lantern another lamp is fitted, and there is a lever switch to direct the current to which ever lamp is required for use. Both lamps have ground glass bulbs, so that the light is soft and diffused, and the circular front to the lantern secures a wide extent of illumination. The convenience of being able to convert the light from ruby to white and vice-versa by a touch amounts

to a luxury, and for making bromide prints or contact lantern slides it is a luxury that few would despise. For the electrical attachment a cord is provided with a plug which will fit an ordinary lamp socket and which may be of any length. The lantern is thus portable, and may be moved to any part of the room, or it may be hung upon a wall. In ordering it is necessary to mention the voltage of the current, so that suitable lamps may be fitted. A lantern of the same design is made for gas, the change between ruby and white light being effected by turning a tap, a bye pass preventing either light from being turned completely out while the other is in use. The upper light is so arranged that the small jet of light is concealed when the light is turned on, so that there is no danger of injury to sensitive material.

The Barnet Printing-out Cards. Manufactured by Elliott and Sons, Ltd., Barnet, N.

For the printing of post-cards and other purposes, where the use of an extremely stout paper or where card is advantageous, Messrs.

Elliott and Sons have introduced a new grade of P.O.P. The emulsion upon this is of the same character as that upon the ordinary grades of gelatino-chloride papers of the same manufacturers, about which we have had occasion to comment favourably on many occasions. The departure simply lies in the support which, as we have indicated, is sufficiently stout to form a post-card. The material is of a beautifully fine hard grain on both sides. The treatment recommended is the same as for ordinary printing-out paper, and the difference in the material for the support of the emulsion in no way entails additional skill to produce a successful result. Whatever advantages there may be in a printing-out process of course are preserved, and undoubtedly there are many who would prefer to produce their work with the characteristics which are even now associated with the idea of a photograph. The new cards may be had with either glossy and matt surface, and for those who prefer to avoid the trouble of toning a self-toning variety is made. The new cards are supplied cut to all the ordinary sizes, including post-card.

The New Rajar $\frac{1}{4}$ Plate Folding Pocket Camera. Manufactured by the Brookes-Watson Daylight Camera Co., Abercromby Works, Great Homer Street, Liverpool.

The term, "pocket camera," is really a justifiable one in its application to this admirable little instrument of the Brookes-Watson Daylight Camera Co., for it can be carried without any great inconvenience in a jacket pocket of the ordinary size, and, to add to its portability, considerable pains seem to have been taken to omit all useless material. At the same time, there has been no sacrifice of strength or rigidity, and particular attention has been paid to

the mechanism of the front, which is exceptionally rigid for a camera of the kind. This, of course, is an especially important matter in a camera fitted with any of the modern flat field lenses, as the perfect correction necessitates exactness of focussing to a degree that was not required with lenses of the older types. The camera body is made of well-seasoned wood, and is covered with finely-grained leather, and there is a sewn leather handle. The fittings are all nickel plated. The focussing movement is a sliding one, and there is an infinity catch, which enables the front to be set at once. The focussing scale has the Cornex index, and the finder is of the rotary brilliant type. The camera may be had with any of the following of Beck's lenses, fitted with a Bausch and Lomb Unicum Shutter; the symmetrical F 8, double aplanat F 7.7, biplanat F 5.8, or the Beck Steinheil Orthostigmat F 6.8. The camera is specially made to take the Rajar film changer, but it will also take dark slides. It seems to us just the camera for the cyclist, for it takes up very little room, and when used with the Rajar changing system there is the advantage that the space occupied by the packs of films is so small that enough can be carried to satisfy the most assiduous of photographic record makers, and, further, that the plague of dusty plates, which can scarcely be avoided, whatever way the plates are carried, is entirely obviated.

Radios Gaslight Bromide Paper. Sold by The Lumière N.A. Company, Ltd., 4, Bloomsbury Street, London, W.C.

The increasing popularity of what are termed "gaslight" papers has led, naturally, to considerable competition on the part of manufacturers to supply the public demand, and the competition which now

exists has stimulated experiment to the extent that the slight difficulties of manipulation, which occurred in the employment of the earlier samples have been successfully overcome, and moreover the surface of the paper itself and the character of the image producible on it have been vastly improved. It would be of very little use nowadays to attempt to sell a paper of a quality anything far short of absolute perfection. Photographers, both amateur and professional, are now keen judges of materials to render such an enterprise other than hopeless. The prints, which were submitted to us, satisfied us that the paper is capable of results which but a few years ago would have been deemed impossible of production by simple development. Even granting that extremely fine negatives had been used, the long scale gradations, the rich deep shadows, and the perfectly pure high light unaccompanied by any suspicion of hardness or loss of the subtle tint of the higher tones, proved that the paper must have been of exceptional quality to produce such results. That equally good results can be obtained by anyone with the exercise of an ordinary amount of skill we satisfied ourselves by the simple experiment of making few prints according to the directions. The exposure with a negative of average density is about one minute to an ordinary gas flame, and the developer recommended is: Water, 20 ounces; anhydrous sodium sulphite, 5 to 7 drachms; dianol, 40 grains; 10 per cent. sol. of potassium bromide, 25 drops. This developer gives a pleasing black tone, inclining to purple, and there is no fear of fog or degradation of whites. The development is rapid, being complete in less than five minutes.

ROYAL PHOTOGRAPHIC SOCIETY COUNCIL ELECTION.

THE following is a copy of the balloting paper:—

President, *Sir W. de W. Abney, K.C.B., F.R.S.

Vice-Presidents (erase not fewer than five names): *Thomas Bedding; *The Right Honourable the Earl of Crawford, K.T., F.R.S.; *Thomas R. Dallmeyer, F.R.A.S.; *P. H. Emerson, B.A., M.B. (Cantab); *Thomas E. Freshwater, F.R.M.S.; *Chapman Jones, F.I.C., F.C.S.; *Joseph Wilson Swan, M.A., D.Sc., F.R.S.; *Major-General J. Waterhouse, I.A.; *Sir Henry Trueman Wood, M.A.

Treasurer: John Sterry.

Ordinary members of Council (erase not fewer than thirty names): *J. T. Ashby; *T. Thorne Baker, F.C.S.; Arthur C. Bear; *Robert Beckett; *Samuel J. Beckett; *Thomas Bedding; *Henry W. Bennett; George E. Brown, F.I.C.; James Cadett; St. Lawrence Carson, B.A., B.Sc.; *Charles Churchill; Leslie E. Clift; Henry E. Davis; *T. Sebastian Davis, F.C.S.; Alfred Ellis; *Douglas English, B.A.; A. R. F. Evershed, L.R.C.P.; *Thomas E. Freshwater, F.R.M.S.; Thomas K. Grant; Dr. Charles F. Grindrod; Haddon; Ignatz Herbst; Sir W. J. Herschel, Bart.; *John Hodges; E. T. Holding; *Francis Ince; G. Lindsay Johnson, M.A., M.D., B.Sc., F.R.C.S.; Rev. F. C. Lambert, M.A.; *George Lamle; Alexander Mackie; Thomas Manly; *J. C. S. Mummy; Charles H. Oakden; *J. Borthwick Panting; *J. I. Pigg; E. W. Prevost; Ph.D.; H. C. Rapson; *P. R. Salmon; A. R. Sargeant; Leslie Self; *E. Sanger Shepherd; *C. W. Somerville; *John Spiller, F.I.C.S.; H. S. Starnes; *Joseph Wilson Swan, M.A., D.Sc., F.R.S.; *Alexander A. K. Tallent; Walter Thomas; Professor William C. Thorne Unwin, B.Sc., F.R.S.; *H. Snowden Ward; *Major-General J. Waterhouse, I.A.; *Benjamin Gay Wilkinson; *Herbert Young, M.A., D.C.L.

Fellows of the Society are indicated by an asterisk.

Balloting papers may be posted at any time, but only those will be counted which are received at No. 66, Russell Square, London, W., by 12 noon on Monday, February 8th, 1904 (the day preceding annual general meeting).

A MEMBERS' meeting of the Professional Photographers' Association will be held on Friday, February 12th, at the rooms of the Royal Photographic Society. On this occasion a paper will be read by Mr. T. C. Turner on a subject of great importance to professional photographers.

The annual supper of the London and Provincial Photographic Association will be held on Thursday, the 18th inst., at the W. Swan Hotel, Tudor Street, London, E.C., Mr. E. J. Wall in the chair. A few tickets remain unsold, and may be obtained of the hon. secretary, Mr. R. J. Kindon, Burnside, Church Road, Shortland, Kent.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
5.....	Aberdeen Photographic Assoc.	<i>A Trip in the French Riviera.</i> Illustrated. Mr. Alex. Adams.
5.....	Plymouth Photo. Society	<i>On the Choice of a Subject.</i> Illustrated. Fredk. Johnson.
6.....	Southampton Camera Club	<i>Colour Photography.</i> Mr. E. Sanger
6.....	South London Photo. Society	Shepherd, F.R.P.S.
6.....	Oxford Camera Club	Telephotography.
8.....	Ilford and District Photo. Soc.	Photography Prize Slides.
8.....	Camera Club	<i>The Use of the Spectacle Lens.</i> Mr. H. W. Dunklev.
8.....	Ulster Amateur Photo Society	<i>The Great Dominion.</i> Mr. Edgar Wallace.
9.....	Royal Photographic Society	<i>Halation, its Cause and Cure.</i> Illustrated. Mr. John Brown, F.R.S., A.M.Inst.C.E.
9.....	Nottingham Camera Club	Annual General Meeting.
9.....	Birmingham Photo. Society	<i>English Cathedrals.</i> Illustrated. Mr. W. Mosley.
9.....	Everton Camera Club	<i>The Making of Enlarged Negatives and Work Thereon.</i> Mr. J. H. Fear.
9.....	Aberdeen Photographic Assoc.	<i>North Wales.</i> Part I. Mr. E. Youds.
9.....	Ashton-under-Lyne Photo. Soc.	Silhouette Photography.
9.....	Photographic Club	<i>Majorca.</i> Mr. G. E. Thompson.
1.....	Gainsboro' Camera Club	<i>Bromide Printing.</i> Demonstration. John H. Avery.
1.....	Glasgow Southern Photo. Assoc.	<i>Carbon Printing and Developing.</i> Mr. C. Marshall.
1.....	Southport Photo. Society	<i>In and Around Glasgow Cathedral.</i> Mr. James Jack.
1.....	Liverpool Amateur Photo. Assoc.	<i>Conversations.</i>
1.....	London & Prov. Photo. Assoc.	Lecture Evening.

1.....	Watford Camera Club	<i>Souerrille.</i>
1.....	Hull Photographic Society	<i>The Capabilities of the X Rays.</i> Illustrated. Dr. Roiman.
1.....	Woolwich Photo. Society	<i>Trimming, Mounting, and Framing.</i> Mr. W. J. Edmonds.
1.....	Camera Club	<i>Hand Camera Work.</i> Mr. A. Horsley
		Hinton.
		<i>More of my Camera Notes on Natural History.</i> Mr. Douglas English B.A., F.R.P.S.
		<i>Perspective from an Architect's Standpoint.</i> Mr. G. A. T. Middleton, F.R.I.B.A.

ROYAL PHOTOGRAPHIC SOCIETY.

The following are extracts from the annual report:—

The principal event in the year under review was the attainment of the fiftieth anniversary of the Society's foundation. The passing of this noteworthy period in the Society's history called for some special celebration, and a congress, reception and dinner were arranged for its honour in the month of May. The proceedings will be familiar to the members through the medium of the JOURNAL. At the reception, which took place at the New Gallery, Sir William Abney, K.C.B., the president, in the course of an interesting address, brought forward a proposal for the institution of a photographic research laboratory, at which, as he pointed out, many questions of great importance to photographic science might be investigated. Further reference to this proposal will be found elsewhere.

At the congress, interesting papers were contributed by Mr. F. E. Jones, Dr. A. Miethe, M. Léon Vidal, MM. Lumière and Seyewetz, and Dr. Jumeaux, and an historical exhibition was opened in the Society's rooms. The celebration of the Jubilee ended with a dinner which was present a large gathering, including some distinguished members of the scientific world.

The Council made the Society's Jubilee the occasion of the election of five Honorary Fellows:—Sir W. de W. Abney, K.C.B., Sir William Huggins, F.R.S., Baron Arthur von Hübl, Dr. E. Valentini, and Dr. S. Czapski, the addition of whose names to the roll marks not only a recognition of the labours of distinguished men, but the Society's more intimate association in the future with prominent workers, at home and abroad, in many fields of photographic research.

The Society was honoured in its turn by the receipt of the gold medal of the Vienna Photographic Society in recognition of its work in the advancement of photography during the past fifty years, with letter of congratulation from its Honorary Fellow, Dr. Josef Maria Herl, writing as president of the Vienna Society. The Council were urged by the members in passing a resolution expressing the feelings of appreciation with which the Society received the award.

The Council are pleased to note a net increase in the membership

amounting to fifty-five. The Society is, however, in need of a much larger membership, and the Council earnestly impress upon the members the importance of interesting in it more of the large body of the public practising photography, with a view to their admission to its ranks.

PRACTICAL DEMONSTRATIONS.

In order to meet the requirements of a section of the members which attaches more importance to practical instruction than to the more advanced theoretical papers brought before the ordinary and technical meetings, the Council have arranged for a series of monthly demonstrations upon printing processes. In view of this decision, the informal meetings, which have not met with the success anticipated for them, have been abandoned and the demonstrations will as far as possible be given on the first Tuesday in each month. Their success seems already assured, and the Council hope that the members will make them known as widely as possible.

THE ANNUAL EXHIBITION.

The Society held its forty-eighth annual exhibition at the New Gallery, which has been secured for a further term of three years. The fiftieth anniversary of the Society's foundation having been attained during the year under review, the Council introduced commemorative features in the form of an invitation pictorial section—as distinct from the established competitive section; and an invitation scientific and technical section—which replaced the ordinary competitive section of that description.

The Council have to thank those members and others who, by their willing co-operation, enabled them to bring together the interesting and instructive exhibits that were shown. The exhibition was inaugurated by a private view and soirée and remained open to the public for thirty-three days, on seventeen of which it was re-opened in the evening, when lantern lectures were given. The Society has reason to be pleased with the attendance, which materially exceeded that of the previous year, and takes first place in the series of four exhibitions held at the New Gallery. The financial aspect is also a gratifying one, notwithstanding the voluntary sacrifice of the south room and balcony which have previously produced a return for space. The selecting and hanging of the exhibits was entrusted to a committee of twelve members, composed of the five judges elected by the members and seven members elected by the Council, instead of by the members, as in the previous year.

The number of entries in the competitive pictorial section was 1,589 from 443 individuals, and the number of exhibitors whose work was accepted therein was 314. There were 25 foreign and colonial exhibitors from the following countries:—Denmark 1, France 2, Germany 3, Holland 1, Italy 2, New South Wales 1, Switzerland 1, Transvaal 1, and the United States of America, 13.

The Council have arranged for the election of seven instead of three judges in the scientific and technical competitive section of the next exhibition, in order that the many different subjects dealt with in the exhibits may find representatives on the jury. The seven judges will also constitute the selecting and hanging committee.

THE PERMANENT COLLECTION.

Several photographs have been acquired for this collection by presentation and by purchase at the annual exhibition. The greater portion was removed to the New Gallery during the autumn to form part of the section devoted to the representation of the progress of pictorial photography.

THE GENERAL PURPOSES COMMITTEE.

Several small committees have been superseded by a larger committee, called the General Purposes Committee, which relieves the Council of much routine work that now comes before them only on report. The committee is composed of eight members and four non-members of Council.

THE PROPOSED LABORATORY.

An important proposal was put before the Society by the president in the course of his Jubilee address. He pointed to the necessity for a research laboratory specially set aside for the elucidation of photographic problems. Such a laboratory ought, he considered, to be found on the premises of the chief photographic society of the country, and he hoped that the Royal Photographic Society would give the matter full consideration. The president was supported at

the Jubilee dinner by Lord Kelvin, who also referred to the proposal. The Council therefore appointed a committee which is devoting careful attention to the question of the possibility of conducting the laboratory as part of the Society's work, and of raising the necessary funds for fittings, instruments and maintenance. The Council are expecting a report from the committee, and a communication to the members will follow in due course.

THE ST. LOUIS EXHIBITION.

In response to the invitation of the Royal Commission for the St. Louis Exhibition the Council undertook to invite exhibits illustrating the scientific and industrial applications of photography for the British section. The committee appointed for this purpose have collected some 250 examples, which should form an interesting feature of the exhibition.

THE MUSEUM.

Many additions have been made to the collection of historical apparatus and examples, and some provision has been made for more effectually exhibiting the various articles now in the Society's possession.

COPYRIGHT.

A new artistic copyright society has been formed with a view to the amendment of the existing copyright laws. The council delegated Major-General J. Waterhouse to represent this Society upon the new body and watch the interests of photographers.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

JANUARY 28TH, Mr. Drage in the chair. The secretary announced that the prize of two guineas for the best paper read during the previous year had been awarded by the donor to Mr. T. E. Freshwater, and that the donor, Mr. S. H. Fry, had intimated his willingness to continue the award, as an encouragement to members to submit papers. Mr. W. Thomas gave a long and instructive lecture upon hand-camera work, illustrated by lantern slides, giving hints as to the best apparatus, modes of using, development of negatives, the use of isochromatic plates, etc.

CAMERA CLUB.

THE Monday lecture last week was by Dr. G. H. Rodman, and the subject was "Photography of Electrical Phenomena." It has long been known that when the discharge from the secondary circuit of an induction coil is made to traverse the surface of a gelatine plate a very wonderful record of the spark and its innumerable branchings is obtained, that from the positive being quite different to that produced from the negative pole. Dr. Rodman has made a great many variations of this pretty experiment, and the results he showed in the form of lantern slides on the screen.

He explained that he did not profess to be a skilled electrician. The exigencies of his profession had caused him to gain a knowledge of X-Ray phenomena, and the possession of a large coil and accumulator had suggested the experiments to which he now called attention. Some of the effects produced seemed to be quite inexplicable; he hoped that those present would be able to enlighten him as to their cause. The matter was one of absorbing interest to him, and he had come before them in the hope of gaining information rather than with the purpose of affording it to others.

The experiments might be placed under two heads, namely, those in which a single discharge had been employed—a spark, the duration of which is supposed to be about the millionth of a second, and those in which he had used a multiple discharge. In the latter case, he had manipulated the commutator of the coil as rapidly as possible, and he supposed that the exposure of the plate might be taken as being above the twentieth part of a second. He had varied the experiments by using sometimes a point, sometimes a metallic brush, and sometimes a hollow sphere—the hollow brass ball taken from a bedstead—as the terminal for the discharge, which was placed immediately over and touching the horizontal gelatine plate.

The arrangement of the apparatus was as follows: The terminal was brought above the gelatine plate, while the plate itself rested upon a sheet of plain glass of much larger area, which acted as an insulator. This insulating surface rested upon a metal support—a tin

tobacco box. In most cases one pole of the coil was connected as already explained with the gelatine plate, while the other pole was in contact with the metal support underneath. He showed rough diagrams of the way in which the various parts were connected up, and also photographs taken by flash light of the complete apparatus.

It would be impossible to give an idea of the exquisite beauty of some of the pictures shown, and even a reproduction in the form of a half-tone block would do them scant justice. They were certainly seen to perfection by aid of the electric lantern at the Camera Club, which is renowned for its great power and splendid definition. The most remarkable of the pictures were those in which coins were placed on the gelatine plate, for not only were they beautifully defined in themselves, the design and lettering of each being faithfully reproduced, but they were surrounded by miniature lightning of extraordinary ramifications. In some cases one coin or two was connected with a pole, whilst the other one was free, and placed a some little distance off, but both were well defined in the photograph. The current seemed to spread itself over both in its effort to run over the edge to seek the companion pole in connection with the metallic plate below. A curious feature was a kind of nimbus or shadow thrown off by some of the coins, and this was a point upon which the lecturer sought information. Endless variations were made by altering the nature of the coins used, and submitting them to the action of the + or - current, with a point, brush, or sphere as terminal to the wire in connection with the coins. Unfortunately there were no electricians present who could give an explanation of these curious effects, but many ingenious hypotheses were advanced by those who joined in the short discussion which followed the reading of Dr. Rodman's interesting paper. The chairman for the evening was Mr. Inwards.

The lecture on the following Thursday was by the Hon. W. I. Allardyce, who chose for his subject the land and the people of which for a long time he has acted as Governor, namely, the Fiji Islands. Some people may happen to know that these islands are small isolated spots in the Pacific Ocean, and that they are part of the Empire upon which the sun never sets, at least never sets at the same time. Other persons are quite ignorant upon the subject, and give no more thought to the Fiji Islands than they do to the possession of the Equinoxes, or any of the other things which are of no immediate commercial importance. It is, therefore, well that there are good-natured individuals who are willing to tell us about some of our distant possessions, and a better exponent of the condition of affairs at Fiji could not be found than Mr. Allardyce, who has lived among the people since 1879.

The sole photographic interest resided in the quality of the slides which illustrated the lecture, and these were unusually good. Especially interesting was the series which depicted the entire business of fire-walking, that strange semi-religious custom which finds its home in one of these islands. By aid of these photographs we were able to watch the building of the great open-air hearth or oven, upon which the ceremony takes place. First, a foundation of big stones above which are piled trunks of trees to form a mighty bonfire. When the wood is reduced after many hours to a cindery state, the logs or what remains of them, are pulled off by aid of ropes made of green vines, and the red-hot stones are levelled by means of the log-pokers. Then the particular tribe whose members are supposed to inherit the gift of fire resistance, walk over the stones, and come no harm whatever. We are sorry that Mr. Allardyce did not offer a theory to account for their immunity, and that the question did not arise during the discussion. But the proceedings terminated at a late hour that there was doubtless a feeling among the audience much as they enjoyed a singularly bright and informative lecture that they must be chary of asking for more. The chairman for the evening was Mr. Henniker-Heaton, M.P., whose name is so well known in connection with postal reforms. For this reason his presence was welcomed by those present with much enthusiasm.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION—LIVERPOOL BRANCH.

A MEETING was held on Friday, January 22nd, 1904, at the Alexandra Hotel, Dale Street, Liverpool. Present: Messrs. G. Watmough, W. F. Smith, J. Saronie, W. Warrington, W. F. Smith, O.

Cooper, W. N. Cowper, T. Vanderbilt, A. Priestly, S. M. Hubbert, A. F. Mowll, hon. sec. The hon. sec. then read two letters he had received from the hon. sec. of the Association, and he was instructed to write and thank him for cartoons and answer some questions in reference to a debate held on the 29th of November, on the use of the term, "platinotype." The next business was to appoint the chairman for the next twelve months. Mr. A. Priestly proposed, and Mr. T. Vanderbilt seconded, that Mr. G. Watmough Webster be asked to continue that office, and being put to the meeting by the hon. sec. it was carried unanimously. It was proposed by Mr. A. F. Mowll, and seconded by Mr. W. N. Cowper that Mr. F. Warrington be appointed branch hon. sec., the members voting unanimously. On the invitation of the hon. sec., Mr. Fell and Mr. Hedges, of the Aristo Co., came to the meeting at nine o'clock, and had a long chat on the methods of American photographers. It was most instructing and amusing, and kept the members in the meeting room until a late hour.

RICHMOND CAMERA CLUB.

JANUARY 28TH.—Mr. Gibson addressed the members on the subject of bromide enlarging. He dealt first with making enlargements, both by daylight and by artificial light. His first experience was with daylight, and he then placed his camera against a window, blocking out all extraneous light and having a reflector held outside; afterwards he used a daylight enlarging camera. The difficulty with daylight enlarging lies in the uncertain power of the light, and another strong objection is the small amount of daylight that the amateur has at his disposal, for which he usually has other uses. Artificial light overcomes these objections, but the results are not always so satisfactory as those obtained by the use of daylight. When using an enlarging lantern, the size of the negative that can be used is limited by the size of the condenser employed, and therefore the great drawback is the expense of the apparatus if enlargements are to be made from anything except a small negative. For softening the paper on the board ladies' black pins are more satisfactory than drawing pins, as they show less upon the print, and therefore leave less to be touched up afterwards. With regard to lenses, he advised a rapid rectilinear rather than a portrait lens, because, the former having greater depth of field, any slight distortion in the negative can be corrected by sloping the board carrying the bromide paper, without much loss of sharpness. Mr. Gibson then spoke of toning prints, and showed a number of prints toned in various ways. He considered the hypo-alum process the most satisfactory, as there is no trouble with double-toning or with obscuring the shadows; but, after all, he considered untoned bromides the most satisfactory, as toning tends sometimes to reduce and sometimes to intensify the print. A soft negative is the best to enlarge from; a weak one can be faked, but a hard one is hopeless. In the matter of exposure, although it might be heresy to say so, he did not consider the usual test strip system satisfactory, as lights and shades vary in different parts of a picture, and therefore it is often difficult to compare densities. He preferred to use a whole sheet. As a developer, he considered metol-hydrokinone the best, but no developer can be satisfactory if used in very cold weather. Finally, Mr. Gibson showed his system of mounting prints temporarily, by attaching them at each corner with bicycle-tyre cement, which allows them to be easily removed from the mount if necessary.

EDINBURGH PHOTOGRAPHIC SOCIETY.

At the last meeting Professor Baldwin Brown delivered a lecture "Composition and Light and Shade in Turner's 'Liber Studiorum'."

The lecturer began by explaining the reasons which led to the selection of the subject for the evening's papers. He had tried to find a theme which, without being photographic, would yet have some bearing on the artistic side of the work done by members of the society. When visiting the Photographic Salon in London during the autumn, he had asked himself the question: What were the qualities in which the artistic photograph differed from the ordinary print? and he found that these qualities depended to a considerable extent on manipulation of light and shade. In the artistic photograph the lights and shadows were brought into harmonious relations, and an effect of unity was secured; whereas in the ordinary print, taken just as the subject happened to come, the lights

and shades were all over the place, and there was no harmony. No artist had ever been a greater master in composition in light and shade than the great English landscape painter Turner, and in none of Turner's productions was this excellence so marked as in the series of plates known as the "Liber Studiorum." Hence the selection of the subject as one bearing on practical photographic work.

An account was then given of the origin and history of the "Liber Studiorum," and of its relation to the so-called "Liber Veritatis," or "Book of Truth," of the seventeenth-century landscapist Claude. Claude's drawings were little more than memoranda of his pictures, and he probably called the collection the "Book of Truth" merely because it contained an accurate record of his various completed pictures; but Turner, who, apart from his art, was a somewhat confused thinker, seems to have imagined that Claude intended to represent in his drawings the whole truth of nature in her various aspects. Turner accordingly girded himself to the task of producing a series of plates which should surpass in the representation of natural truth all that Claude had accomplished. The task was easy enough, for in the first place Turner's knowledge of nature in all her myriad aspects was infinitely greater than the knowledge possessed by Claude; and, in the second place, while Claude's drawings, which had been reproduced in slight mezzotints by Richard Earlom, were mere sketches, Turner aimed at producing more elaborate and finished landscape studies, and invoked for aid on the copper plates the best available talent among the engravers of his day.

The technical character of the "Liber Studiorum" was then explained, and it was shown that Turner used a combination of etched line with mezzotint for the light and shade. Some of the etched plates before any light and shade was added were shown on the screen, and it was pointed out how masterly was Turner's use of line in order to convey the truth of the skeleton or structure of natural objects. His mountain drawing in the etching called "Ben Arthur," and his tree drawing in "Near Blair Athole," were especially noticed. In the slides of a number of the completed "Liber Studiorum" plates, which were then thrown on the screen, attention was primarily directed to questions of composition and light and shade, and Turner's constant use of repetition as a means of securing unity and repose was illustrated in many examples. The masterly representation of natural truth in the forms of water and clouds and trees was also illustrated, and the variety of the aspects of nature presented in the work as a whole insisted on. It was evidently Turner's main intention in the work to display nature in all her moods, and this was the reason why he was always so anxious that the work should be looked at as a whole. Reasons were given for dissenting from Ruskin's view that Turner intended to preach in the "Liber" any sermon on the passing away and failure of human achievement, and it was found as the plates were passed in review that some of the most beautiful were those in which there was nothing but pure artistic composition, without any pronounced meaning or intention of an intellectual kind. Plates of this kind, such as "Hindoo Ablutions," "Hindoo Devotions," and "The Bridge in the Middle Distance," were among the most successful in the whole collection.

ROYAL Photographic Society.—The following is a copy of the balloting paper for the election of Judges for the Exhibition, 1904. Pictorial section (erase not fewer than thirteen names): J. T. Ashby, F.R.P.S.; Harold Baker; Henry W. Bennett, F.R.P.S.; W. R. Bland; Walter L. Colls, F.R.P.S.; J. Page Croft; William Crooke; P. H. Emerson, B.A., M.B. (Cantab), F.R.P.S.; John H. Gash; C. Barrow Keene, F.R.P.S.; Rev. F. C. Lambert, M.A.; Percy Lewis; Llewellyn Morgan, M.D.; F. J. Mortimer; J. C. S. Mummary, F.R.P.S.; G. A. Storey, A.R.A.; B. Gay Wilkinson, F.R.P.S.; W. T. Wilkinson. Technical and scientific section (erase not fewer than seventeen names): Sir W. de W. Abney, K.C.B., F.R.P.S.; T. Thorne Baker, F.C.S., F.R.P.S.; T. Bedding, F.R.P.S.; Henry W. Commercial & Legal Intelligence

SPEAIGHT, LIMITED.—The above-named company has been registered with a capital of £30,000 in £1 shares. Object, to adopt an agreement with F. W. Speaight and R. N. Speaight for the acquisition of the business of photographers, photographic-artists, portrait and miniature painters, and otherwise, carried on by them at 178, Regent Street, W., as F. and R. Speaight, and to carry on the same and the business of manufacturers and importers of and dealers in photographic materials, chemical, industrial, and other preparations, articles, and compounds, etc. No initial public issue. F. W. Speaight and R. N. Speaight are managing directors, and each may retain office while holding £10,000 shares. Ordinary qualification, £100. Registered office, 178, Regent Street.

At the Westminster Police Court on February 1st, William Morrison Crouch, 47, a photographer, of Ebury Street, S.W., was again before Mr. Horace Smith on remand, charged on a warrant with obtaining money by false pretences from a number of young persons who had paid premiums to be taught the profession. Mr. William Lewis prosecuted on behalf of the Treasury. The case has occupied a considerable time, and the allegations against the accused are that he did not adequately teach his business to a number of young ladies and gentlemen. By advertising he was brought into communication with them or their parents, and in several instances premiums of £20 were paid. The pupils had little or nothing to do; for some time defendant had not a camera on his establishment. One young lady said that they played about, the greater part of the day, and that defendant sat in his arm-chair smoking cigarettes and reading newspapers. He obtained a clerk—with a premium of £25—to do the clerical work in connection with a photographic employees' bureau, but the clerk declared that no real business was done. The defendant received a few letters, enclosing half-a-crown as registration fee. There were no books for weeks after the clerk went in, and the defendant never took the trouble to dress his shop window, even when he had a considerable staff in his employment. Mr. Horace Smith again formally remanded the accused prior to committal to the sessions.

At the Sheffield County Court, before his Honour Judge Mansell Jones, on January 29th, Frank Rogers Baker, 42, Daniel Hill, Sheffield, trading as the Atlas Advertising Company, claimed from H. Howard, High Town Road, Luton, photographer, £2 10s., the second year's rent for an advertising space in a cabinet at Luton. A counterclaim was set up by the defendant for damages for breach of contract to erect and maintain a properly protected advertising cabinet in Luton, for alleged damage caused to photographs, and for loss of business by reason of the defective condition of the cabinet. The defendant also claimed the return of the sum of £2 10s., the total counterclaim being £10. Mr. W. Anty appeared for the plaintiff, and Mr. H. W. Lathom (Luton) defended. The evidence on behalf of the plaintiff was to the effect that an order was given by the defendant that he would take a space in a show case at Luton for the purpose of exhibiting photographs. It was alleged that the space was taken for two years, and one year's rent had been paid. A barometer was placed in the case as an attraction, but it was admitted that this had not been regularly attended to. The defence was that the agreement was not carried out, inasmuch as the case was not put in the position indicated, that it was not watertight, and that the weather damaging the defendant's photographs, his reputation as a professional photographer was injured. The defendant stated that he had an idea that he was signing a contract for two years. He did not read the document which he was asked to sign; he thought it was an order form. His Honour gave a verdict for the defendant on the claim, and for 5s. on the counterclaim.

At Bracebridge on January 29th the adjourned inquest was held on the body of William James Pacey, printer, 125, High Street. Deceased was found dead in his house on Thursday week. Mrs. Alice Pacey, widow of the deceased, said her husband had not been working at his trade, that of a printer, since January of last year, when all the printers had to leave. He took a fried fish business in February. Witness had recently lost her father and mother, who lived with them, and deceased had been very depressed. Deceased

was very fond of photography, and kept the chemicals in a cupboard in the room where he died. On Wednesday of last week the thought deceased had gone to the shop, but found after that he had been seen on the Nettleham Road. He looked very bad when he came home at night, nearly 11 o'clock. He got up about 1 o'clock on Thursday morning, but did not touch his breakfast, and on her remark, "It is very cold," made no reply. Witness left in the house reading while she went in the yard, and when she came back he was stretched out on his chair. Dr. Jagger said the poison brought to him a bottle described. It contained a fairly strong solution of cyanide of potassium, and would probably be diluted further for use in reducing or toning photographs. It was an intensely deadly poison. Replying to the coroner, witness said it was the poison of which Mr. Whitaker Wright died. Examining the stomach, witness found it contained a very copious quantity of cyanide of potassium. There were cases on record where a man had had time to drink from a bottle and put it in the cupboard to conceal it before the poison took effect. Witness did not examine the fragments of the cup, his suspicion not being aroused at the time of his being called. Replying to the coroner, witness said the poison would be in a form which would probably be bought by this man without signing for. There was enough poison in the bottle to kill hundreds of people. The Coroner: Rather a dangerous knowledge to get abroad. The jury found that deceased had committed suicide by taking cyanide of potassium while in a state of temporary insanity.

A SOMEWHAT remarkable "scene" took place in Southwark Court on Monday last, the plaintiff being Helen Mabel Henshaw, young lady clerk, and the defendant Florence Neville, also young lady clerk, of Newington Causeway. It appeared that the plaintiff had lived with the defendant, and after she left she entered an action for the return of a picture or its value which was placed at 30s. The defendant, instead of returning the picture, paid 30s. into court, and thus settled the claim. The plaintiff, however, did not want the money, and now she applied to his Honour Judge Addison, K.C., for an order against the defendant to deliver up the picture. She stated that it had belonged to her mother, now dead, and no amount of money would purchase it. The defendant, however, carried the picture in a piece of brown paper under her arm, handed it up to his Honour, at his request, and said she kept it as security for a loan advanced to the plaintiff. "It is not," she continued, "that I wish to keep the picture."—His Honour: No, I don't think anybody would want to keep that picture.—The plaintiff: I don't owe her a farthing, your Honour.—Well, are you prepared to pay 10s., and secure this invaluable picture?—The plaintiff: No, because I don't owe it.—His Honour: Oh, very well then. I can't help you. You entered your action in wrong form, and she has accepted the value you have placed upon it. But nobody in the world, except somebody who had a very particular fancy, would value it at 30 pence. It is a rubbishy photograph—a most dismal picture. How came you to leave the picture with her?—The plaintiff: Because she gave us only half an hour in which to pack up and clear out.—His Honour: You tell me that this picture which harrows your soul is invaluable, and no money would buy it, and yet you won't pay to recover it. The action was dismissed. The parties left the court, but in the passage the plaintiff and her brother tried to snatch the picture from the defendant. The latter called the aid of the police sergeant on duty, and he separated them, ordering the plaintiff to get her brother off the premises. A cab was procured by a lady friend who accompanied the defendant, and they both entered. The plaintiff rushed to the vehicle, and implored the defendant to give her the picture, and accept the 10s. The defendant was obdurate, and drove off with the mysterious but invaluable picture.

At the Sunderland Petty Sessions last week, Mr. T. E. Pamphill, presiding, John Stewart Cree was charged with obtaining by false pretences 5s. and a photograph from Sarah Craggs at Southwark. Mr. W. W. Moses prosecuted, and said that, although only a charge was preferred against the accused, he could have preferred at least a dozen of the same kind. The prisoner set himself up as the managing director of a company he called the Anglo-Scottish Benefit Art Company, and went canvassing for orders, producing cards on which his name and address, 16, Suddick Street, Sunderland, were printed as manager of this company. He pretended to supply an enlarged photograph for a certain figure on a cabinet photograph

ing lent him, and a deposit paid him. He undertook to deliver the enlarged photograph in fourteen days, and kept on collecting instalments. But the enlargement was never seen. In fact, he worked a grand system of fraud.—Sarah Craggs, No. 1, Broad-street Terrace, Southwick, stated that on September 29th last year the prisoner called at her place at Castletown, and stated that he presented the Anglo-Scottish Benefit Fine Art Co., of which he had previously left her a card which advertised himself as the managing director. He undertook to enlarge for her a photograph for 15s., and, believing the company genuine, and the prisoner what he represented himself to be, she gave him a cabinet photograph and paid him a deposit of 3s. The deposit was entered on a card, and the receipt signed by the prisoner, who said the cabinet would be returned in three days, and the enlargement in fourteen days. On October 10th and 24th witness paid further instalments of 1s. each, and it was entered on the card, but since the last date she never saw him again until the Sunday following Christmas Day, when she met him in Edward Burdis Street. She asked him for the photograph, and he said he had sent away for it, and witness would wait it as soon as he received it. But neither the original photograph, nor the enlarged photograph, nor the money she paid had been delivered.

Amy Nash, 6, Oswald Terrace, said prisoner called at her house on September 29th, and, representing himself as in the previous witness's cases, she gave him an order and photograph and a deposit. He paid several instalments, and eventually paid the whole sum, and was promised the enlargement. She, however, never got it.—Mary Ann Stafford, of Castletown, gave similar evidence.—John Elliott Peace, printer, Stoney Lane, Southwick, spoke to having printed, on September 23rd last, 1,000 cards similar to the one left at Miss Craggs's place. When he ordered the cards, prisoner explained to witness that the "company" was opening out a branch at Southwick, and he was the managing director. The cards were printed and delivered, but witness was never paid for them.—Inspector Cowan, of Southwick, deposed to arresting the prisoner on a warrant at 1.30 a.m. on Wednesday last. Though prisoner repeated his address on the cards at 16, Suddick Street, it was really The Terrace. At the address where witness arrested the prisoner, he found photographs (produced), amongst which was Miss Craggs's. Prisoner pleaded not guilty, and chose to be tried there and then. He said there was no fraudulent intention on his part, and he had dealt fairly with the people. Several photographs were awaiting delivery, but, unfortunately, Miss Craggs's was not one, he having returned her enlargement because it was not satisfactory. He had delivered many enlarged photographs.—The Bench found him guilty, and, in sentencing him to three months' imprisonment with hard labour, expressed their opinion that it was a most impudent swindle. *Sunderland Daily Echo.*

At West Ham Police Court on February 1st, George Sanders, a dealer in fancy goods, etc., of 80, Victoria Dock Road, was summoned before Mr. A. Gillespie to show cause why an order should not be made for the destruction of a large quantity of obscene pictorial postcards, stereoscopic slides, books and writings, found on his premises. Mr. H. G. Muskett appeared for the Commissioners of Police, and Mr. T. Griffith Davies represented the defendant. Mr. Muskett in opening the case said, that according to his own description the defendant carried on "a bazaar of nevelties." Complaints were made to the police as to the nature of the business, and as a consequence, observation was kept on his shop by the police. A great number of boys went there to purchase pictorial postcards of an offensive character. On December 30 an officer went to the shop and brought some of these postcards, with the result that on January 8 a warrant was issued for a search of the premises. When this was executed on the night of January 8th, 750 postcards, 43 books, and a number of other works were seized, and for the destruction of these an order was now asked. He (Mr. Muskett) had a good deal of experience in matters of this kind, and he must say that never before had he seen postcards of such a peculiarly offensive character. In addition to these there were a considerable number of books of an obscene character, and these indicated that the defendant was carrying on the business of an obscene bookseller. Detective-sergeant Eustace deposed to executing the search warrant. The defendant's shop on one side was devoted to the sale of picture postcards and books, and on the other side were fancy goods and china, but there was no counter. From the interior of the shop and from

the windows the witness seized 1,025 pictorial postcards, and he also took away 43 books, some of which were in the window; a home cyclopaedia which had some plates in it, and 30 stereoscopic slides as well as some commonly known indecent books. In an upstairs room were some so-called comic pictures, and a number of rhymes in MSS., which the witness thought were of the filthiest character imaginable. Mr. Griffith Davies submitted that some of the books were really medical treatises, which might be bought by the general public in pursuit of science. Mr. Gillespie: Why should the public require these books at all? He is a china dealer, and sells these things to anybody. After some further discussion Mr. Gillespie said that the question of whether or not things were obscene depended on circumstances. In the present case he should hold that the postcards, stereoscopic slides, and books and writings were obscene, and he would make an order for the destruction of the whole lot. Mr. Muskett asked for costs, and his worship made an order for the payment of £4 4s. costs. Two other summonses charging defendant with exposing 39 indecent pictorial postcards in the shop window and 36 in the interior of the shop were then heard, but after some legal discussion Mr. Muskett said he would be content to rely on the summons for the exposure in the shop window, and withdraw the second summons. Mr. Griffith Davies said the defendant would plead guilty to the exposure of the goods with reference to which he pointed out, his worship had already adjudicated. The defendant had to lose his goods and pay £4 4s. costs; that he submitted would meet the ends of justice. Mr. Muskett said he could not agree with that suggestion. Many of the postcards were "a hundred per cent. worse" than any he had ever seen before, and he asked his worship to exercise his power in such a way as to afford a warning to other dealers in such goods. Mr. Gillespie said he was not going to inflict the full penalty of three months' hard labour, but he looked upon this matter very seriously. The sale of such things was most harmful, and here the sale was general and most deliberate. For exposing these postcards in the shop window the defendant would go to prison for one month with hard labour.

News and Notes.

THE proprietors of the "Graphic" have invited the Applied Art Section of the Society of Arts to visit their new printing offices in Tallis Street, Victoria Embankment, E.C., on Thursday evening, February 18, from 8 to 10.30 p.m., when the various processes in the production of an illustrated paper will be shown in operation. As the accommodation is limited, not more than 100 cards of invitation will be issued. These cards will be issued in order of application to members of the society until the number is exhausted. Any member who desires a ticket should apply at once. Each ticket will admit the bearer and one friend. No one can be admitted without a ticket.

ST. LOUIS EXHIBITION, 1904.—The Commercial, Labour, and Statistical Department of the Board of Trade has prepared a number of diagrams dealing with various branches of labour and trade statistics, to be exhibited in the Social Economy Section of the forthcoming Exhibition at St. Louis. The diagrams (twenty-eight in all) are intended to illustrate the statistics of employment, wages, prices, production, consumption, foreign trade, shipping, railway traffic, trade disputes, trade unions, workmen's co-operative societies, industrial accidents, and pauperism. Those interested are invited to view the exhibits at the Labour Department, Board of Trade, 43, Parliament Street, S.W., on Wednesday or Thursday, between 12 noon and 6 p.m.

MR. SAMUEL P. JACKSON, whose death occurred last week at Bristol, was an artist of some note. He was born on September 12, 1830, his father being an artist and an Associate of the old Water Colour Society. Mr. Jackson became an Associate of the same society in 1852, being the youngest Associate ever elected. His favourite subjects were scenes on the Thames, in North Wales, and on the Cornish coast. He exhibited on several occasions at the Royal Academy, and three of his drawings are in the South Kensington Museum. Mr. Jackson, who was of a retiring disposition, had not painted since 1900. His tastes were scientific as well as artistic, for he was the inventor of an instantaneous shutter which obtained a silver medal awarded by the Royal Photographic Society.

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon, the 1st

instant, Sir James Crichton-Browne, Treasurer and Vice-President, in the chair. Mr. W. B. Bryan, Mr. C. E. Challis, Mr. A. F. H. Dick, Mr. W. Gowland, Sir Charles Hartley, K.C.M.G., Miss C. Jones, Mr. C. E. Layton, Mr. C. F. Lan-Davis, Mr. H. Loeffler, Brigade Surgeon Lieut.-Col. C. W. MacRury, Mr. W. M. Ogilvie, Mr. C. G. P. Pownall, Lady Priestley, Mr. C. F. Rousselet, Mr. R. E. Tatham, and Mr. J. Weir. The special thanks of the members were returned to Sir Andrew Noble, Bart., Dr. Frank McClean, Mr. J. B. Brönn-Morison, J.P., and Lord Greenock for their donations to the Fund for the Promotion of Experimental Research at Low Temperatures.

ACCORDING to a Paris correspondent some interesting facts came to light in the first Court when an action for damages brought by the Comte de Leontieff against a cinematograph company was heard. The company in question approached Comte de Leontieff, Governor-General of the Equatorial Province of Abyssinia, on the subject of taking a series of cinematographic views of the Emperor Menelik, his Court, military entourage, and of all the public and private phases of Ethiopian life. Comte de Leontieff, with his staff, which he had brought from Paris waited, but in vain, as he alleges, for the operator which the company had put at his disposal. He further alleges that the non-execution of the contract meant a loss to him of £1,600, without reckoning other benefits if the work had been executed. "I have myself been put to considerable expense," he added. "When I arrived at Addis Ababa, I obtained the consent of the Emperor Menelik for the complete execution of the work, but in accordance with the customs of the country I had to offer the Emperor two guns with their accessories and 44,000 cartridges, which cost £1,200, and to Ras Makonnen 500 Berdan rifles, as well as 50,000 cartridges, at a cost of £1,000. Comte de Leontieff estimated that altogether the loss rose to £8,000. After hearing the pleadings the Court agreed in principle to the Governor-General's demand, but reduced his claim to £1,800."

A Correspondent writes: "There can be no doubt that the trend of events is in the direction of making the metric system of weights and measures compulsory in this country. Whatever weighty arguments, and they are many, that can be advanced against the system on account of its want of elasticity for daily intercourse of buying and selling, and measuring, the fact remains that our chief commercial rivals employ it, and our own system does not stand the test of usefulness when placed side by side. The Journal of the Royal Statistical Society for December 31st last contains an important paper on the system by Mr. Alexander Siemens, together with a report on the discussion. It is illustrated by tables showing the trade of metrical and non-metrical countries for the year 1900, that year marking a culminating point in most countries. Mr. Siemens puts forward powerful arguments in favour of adopting the metric system, and concludes by saying that 'it is quite certain that the action of Great Britain in this matter would immediately be followed by Greater Britain, the United States, and Russia, so that international unity of weights and measures would become an accomplished fact for which James Watt started his agitation 120 years ago.' If only for one cause alone its compulsory adoption would be advantageous in photography in avoiding that terrible duplication of figures which appears to be a necessity in all photographic formulæ. It might lead, though we scarcely dare hope so much, to a simplification of formulæ, especially in the direction of mutual comparability."

SILVERED-GLASS MIRRORS.—The days of the old mercurial-tin-amalgam have gone by, and virtually all mirrors are now made by deposition of metallic silver upon glass; indeed, so low down is the process worked that we have seen mirrors of which the glass itself was so full of streaks and marks that the mercury process would be well-nigh impossible upon it. In the earlier days when large areas were silvered a prejudice existed in favour of the old method on account of the less nearly perfect colour and lustre of the "chemical mirrors," but all those difficulties have been surmounted, though to some extent there are trade secrets governing the use of the process. Any variation in the wrong direction in the colour, for example, of a 3ft. reflector for a telescope would make an appreciable difference of exposure, although in the case of a reversing mirror for process or other work such divergence might be ignored, perfection of surface in the deposit being the main elements of interest. Still some observations by M. Leo Vignon, which appear in the bulletin of the

French Chemical Society on this subject are very interesting. He has observed that very small quantities of copper, such as that present in distilled water made with a copper retort, have an influence on the silvering of glass. The results of his experiments show that the presence of a very small quantity of copper (0.08 milgrm. per litre) facilitates the operation by lowering the temperature at which the mirror is formed. A higher proportion of copper alters the colour of the mirror, and may even prevent its formation.

PHYSICAL SOCIETY NOTES.—At the last meeting in January of the society there were two optical papers read containing many points of interest to those who make a study of the optical aspects of photography, but which are too complex to be capable of brief summarisation, and a third on the all-pervading subject of radium, which has a special photographic interest. This was by Mr. S. Skinner, and though not actually read at the meeting, has been summarised in the "Chemical News":—"It is well known that a photographic plate by exposure to radium rays is affected in such a way that the plate develops similarly to its development after exposure to light. The experiments described in the paper are an attempt to answer the question: Are the actions the same? As far as can be seen, the final results of the actions and developments are the same, and the experiments appear to indicate that only slight differences occur in the early stages. The plates, suitably enclosed, were subjected to the rays from varying quantities of radium bromide for varying times and the results showed that the intensity of the developed image increased rapidly to a maximum value with increase of exposure, then decreased, first rapidly, and, finally, very slowly, until a stage was reached in which there was practically no dark image formed on development. It is found that spark images are, at first, obliterated by radium rays, which do not cause such a great density as that of the spark images obliterated, and that with prolonged exposure the radium rays reverse the spark images."

CRISTOID FILMS.

To the Editors.

Gentlemen,—We see that one of your correspondents, "Phil," in the issue of the 22nd ult., is inquiring for a film other than celluloid impervious to damp and noninflammable. You reply that the cristoid film is non-inflammable, but not impervious to water. May we point out that after development and drying the cristoid film may be easily rendered waterproof by a coating of waterproof varnish such as we supply?—We are, yours faithfully,

SANDELL FILMS AND PLATES, LTD.

Norwood Junction, London, S.E.,
January 27th, 1904.

BARIUM HYPOSULPHITE.

To the Editors.

Gentlemen,—In reply to Mr. Trevor Grant's query re the solubility of barium hypo, I beg to state that I have found it to be "practically insoluble." Having washed a quantity of the precipitated salt on filter; the washings on evaporation yielded but a very slight residue. The matter should be of great interest to all photographers, and I am looking forward to further information on the subject.—Yours faithfully,

PHILIP E. BELLAIR.

Royal College of Science, St. Stephen's Green E., Dublin.
January 26th, 1904.

FIXATION IN DAYLIGHT.

To the Editors.

Gentlemen,—In your last issue we notice an extract from a paper read before an American photographic society, advocating the fixation of negatives in daylight.

you may remember that, when we introduced our Pocket Dark, last year, we recommended the procedure in question, and our demonstrations we usually cause some mild consternation by moving developed negatives from the Pocket Dark Room to the light bath in broad daylight. However, providing that the developer has been thoroughly washed off, there is no danger whatever. It is advisable, of course, that there be no undue delay in placing negatives in the fixing solution.—We are yours truly,

The Pocket Photography Co., Ltd.,

J. W. MEER.

The Pocket Photography Co., Limited,

56, Gracechurch Street, and Talbot Court, London, E.C.,

January 28th, 1904.

COLOUR-VISION.

To the Editors.

Gentlemen,—In his thoughts on colour-vision, your contributor, "Festina Lente," introduces the subject of "colour-vision in the light of the doctrine of evolution," and inquires "at what stage in the evolution of man was this power developed?"

May I be allowed to point out to "Festina Lente" that colour-vision is developed and utilised by the lower animals at the present day, and more especially, perhaps, among insects, as butterflies? Before, man alone does not possess this special faculty of colour-vision. Consequently, it has not been specially evolved as a sense of colour-perception with the evolution of man, but already existed among those ancestors from which mankind presumably sprang.

There are also geological evidences of the existence of butterflies and other insects, and also flowers (presumably coloured to attract insects, as at the present day), very, very long ago—in fact, geological ages before the appearance of prehistoric man upon the earth. This at once disproves the suggestions of your contributor—colour-vision was acquired accidentally in man, and also other of your random thoughts.—Yours, etc.,

HARRY QUILTER.

Leicester, January 30th, 1904.

OVER-PRODUCTIVENESS IN PHOTOGRAPHY.

To the Editors.

Gentlemen,—I heartily agree with Mr. J. Page Croft, in what he says concerning the future possibilities of old negatives. Indeed, he reminds me of seeing, in a contemporary, a recent article of mine in which the saving of all rejected negatives and prints, with a view to their examination by the light of a better cultivated judgment, in the future, to come. He is mistaken in thinking that I ever advised a wholesale smashing of past results. I only, half jestingly, advocated a course in the case of a medalled picture, after one print of undoubted permanency has been secured.

I am sorry to trespass on your valuable space any further, but as your printer has unfortunately made nonsense of a sentence in my letter to Mr. Spackman, you will, no doubt, be kind enough to repeat to me I already have had several inquiries concerning it. The paragraph should run as follows:—"It is precisely the fact that the prints obtained from the same negative, if controlled and manipulated as delights the heart of the pictorialist, can be exactly alike, and thus forms one of the strongest arguments against duplication."—

Gentlemen, yours very truly,

A. LOCKETT.

Brook Street, Kennington, S.E.

January 29th, 1904.

EXHIBITION AT BRIGHTON.

To the Editors.

Gentlemen,—I should be glad if you could announce the forthcoming Photographic and Bioscopic Exhibition to be held at the Brighton Aquarium, March 9th to 26th inclusive, under the control of the Corporation.

It is proposed to let spaces for the erection of stands for the sale of the trade to enable firms to introduce their new specialities during the coming season; also competitions, particulars of which are as follows:—

Competitions.—Open Classes.—A. Landscape, river scenery, and marine. B. Portraiture and figure studies. C. Architecture. D. Still life. E. Animal studies.

Lantern Slides.—F. Landscape, river scenery, and marine. G. Portraiture and figure studies. H. Architecture. I. Flowers and still life. J. Animal studies. K. Scientific and examples of colour photography.

Special Class for Sussex Schools.—L. Prints (any subject). M. Sets of four lantern slides.

These classes are only open to pupils at present attending day and boarding schools. Silver and bronze medals and diplomas will be awarded at the discretion of the judges. Entry forms and further information respecting the Exhibition can be obtained from the General Manager, Aquarium, Brighton.—Thanking you for your kindness in giving notice in your journal of this Exhibition, I am, yours faithfully,

WILLIAM J. HARDY,
Manager.

Brighton Aquarium.

RESIDUES.

To the Editors.

Gentlemen,—Re your remarks as regards saving residues in last week's JOURNAL, I always have thought that it is advisable and profitable even in the smallest business, if we can depend on getting our honest dues from the refiner. But this is the crux. There seems no possibility of knowing anything about it, and yet, one would think dried sulphide, for instance, would contain an assured quantity of metallic silver. My personal experience with refiners has been various and not always satisfactory. If one sends, as I did last year, over a pound of dried sulphide of silver to be melted, and then to receive 5s. 4d. for it, less the fee for melting, the game is not worth the candle. In spite of the editorial "placets" so often given to grumblers over unsatisfactory returns of refiners, I place very little confidence in them, and in future intend to buy a crucible and melt my own residue by way of testing the thing. From my various invoices obtained from refiners, and from my own notes thereon concerning quantities sent, I find that the average of my sulphide parcels is about 1 in 5, that is, 1oz. of silver contained in 5oz. of dried sulphide free from foreign matter. If one could always get this it would pay, as a pound of sulphide would then with silver at, say, 2s. 2d. per oz. produce about 7s. I am extremely doubtful whether ashes of silver paper are worth saving. My record of this is that 29oz. ashes of P.O.P. and C.C. contained .550 silver, valued at 1s. 3d. Perhaps the best way would be to fix out the scraps and reduce the silver from the hypo. I do not think it would be so expensive as paying for melting the ashes. I may say that a pound of liver of sulphur, which costs 9d., should be ample to reduce the fixing baths of a small business for a year, and should easily produce 20 to 30 oz. of sulphide.

—Yours faithfully,

February 1st, 1904.

OTHELLO.

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—I read with great pleasure the item, "How to adopt the metric system," you reproduced from the "World's Work." This new way is very interesting indeed, and it is of not much use to dispute the rough figures of 550 and 450 millions of people. The larger figures may include a few hundred millions from India and Africa, which have no idea of metre or pound; but figures tell, and as China will probably be English some time or other, we may as well add 400 millions to the 550 above mentioned. However this may be, I do not hear of the 450 millions (minority of some account) complaining of the actual state of things. On the other hand, I read of the difficulties the English experience sometimes, and, more and more, in their transactions with foreign countries, just on account of the measures and weights as used by them. It is true, the English will be saved, so it is said, a terrific and useless (why?) sacrifice, but the "World's Work" forgets to give a valuable reason why this terrific and useless (certainly) sacrifice should be imposed on the poor 450 millions of people. So far as I am aware, I have not seen any complaints arising among these 450 millions, and any wants to go to the English system of inches, yards, pounds, ounces, drams troy, etc., etc., etc. I have, however, heard of a very few millions of people in the United States of America (75, I think) asking for the metre and kilo system, as they already have for their

money transactions. I know of a much better way out of the difficulty, and all will save this terrific and useless sacrifice. Let the paltry 450 million people dabble in their mistaken metre and centimetre, and the 550 millions keep aloft with the very shortly universal inch measure. The power is reserved, so the "World's Work" says, to English inch length unit, while the centimetre is doomed to obliviousness. Let us wait with patience, with very much patience, and maybe our great-grandchildren may see it or, maybe the reverse, much sooner.—Yours very truly,

A. LEVY.

Asnières, Seine.
February 1st, 1904.

MESSRS. WELLINGTON AND WARD'S PICTORIAL ADVERTISEMENTS.

To the Editors.

Gentlemen,—As many of our friends have written us asking the meaning of our new pictorial advertisements for 1904, we should be much obliged if you could devote a small space to an explanation.

The plot is as follows, and if you would like to have the original designs for your personal satisfaction we will send them up to you with pleasure:—

Lame Lancelot, being unable, by reason of his affliction, to see the world for himself, the Art of Photography brings it to him. He is so far carried away by the realistic presentiments in the book of photographs which the Genius of Photography hands to him in the first scene that he fancies he personally is taking part in the different scenes brought before him. Pictures of Arctic lands seem to transport him thither; the contents of galleries and museums are brought faithfully to him. It brings crowned heads, politicians, and celebrities of all kinds to him so realistically that he thinks he meets them personally. It was by the means of photography that all the world knows the crown of Soutapharnes.

The Mermaid refers, of course, to the more prosaic inhabitants of the sea. Photography also brings before us the minutest details of certain geniuses, such as botany, etc.

The X-ray discovery of the pebbly heart brings in (an exaggerated fancy, of course) an important branch of photography, and paves the way rather prettily to the last scene, where Lancelot falls in love with the photographic image of his fate.

And so, though Lancelot could not go out into the world to gain his experiences, photography brings it to him.

It is an extravaganza, of course, and so the "long bow" can be drawn with discretion, and we must see only from a photographic point of view.—We are, yours faithfully,

Wellington and Ward,

H. W. HALL, Manager.

Elstree, Herts, January 25th, 1904.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors

Gentlemen,—Mr. H. O. Klein's statements are of such a character that we are afraid we cannot allow him to rest "fully satisfied," and we shall be glad of your permission to again point out some of his inconsistencies.

In his letter in your issue of January 15th, Mr. Klein specifically stated, "every operator whom I have had the pleasure to teach the use of these preparations for trichromatic work, and every teacher of collodion emulsion, both here and abroad, with the exception of the lecturers, will confirm my statement, that sensitiser C produces practically the same speed as A sensitiser." On our demonstrating that with arc light reflected from white blotting paper the ratio of A to C, even when at its maximum speed after several weeks maturing, was *not* the same, but as 5 to 9, Mr. Klein actually has the effrontery to say that "this practically confirms my ratio of 1 to 2," and to add that "this corresponds with the tests made to incandescent gas light exactly as I anticipated." But his tests were not made to incandescent gas light, but to incandescent electric light, according to the type-written statement sent to us with the tests, and they did not prove the C to be only half the speed of the A, but about eight times faster!

Then, again, Mr. Klein stated in his first letter that the relative exposure in three-colour work for the red printer (A) to be 0.5, and

for the blue printer (C) $1\frac{1}{2}$ or 2, that is a ratio of 1 to 3 or 4. In his second letter he says, "my ratio is 1 to $1\frac{1}{2}$ or 2"! We cannot see what advantage Mr. Klein hopes to gain by these puerile permutations, for any one interested is certain to read the correspondence carefully, and at once detect the discrepancies.

Mr. Klein states that he is "an absolutely independent worker who has no more interest in the subject than any other person." Now, since we expressly suppressed any reference to Mr. Klein's financial interest in emulsion, this remark is uncalled for, and, moreover, is not true, in the usual acceptance of the words. For surely anyone in paid employment, we believe, almost exclusively devoted to preparing collodion emulsion and demonstrating its working, cannot by any stretch of imagination be said to be disinterested.

It would appear to be beyond our ability to overcome Mr. Klein's peculiar "difficulty to understand why we used the light we did. However, we will try and put it simply once more. We wanted light that was fairly constant, and that would give a continuous spectrum. Then we ascertained the speed values to this light of the various plates tested in order that they might receive an exposure to the spectrum relatively corresponding, so that the comparison of colour sensitiveness, which was our ultimate object, would be quite fair.

Further, incandescent gas light happens to be the very light recommended by the inventor in the pamphlet issued by the maker of the spectrum camera we used, this form being the one with whom Mr. Klein is employed.—Yours faithfully,

A. J. NEWTON.

A. J. BULL.

PHOSPHORESCENCE OF PHOTOGRAPHIC PLATES.

To the Editors.

Gentlemen,—Although this phenomenon may be new to Mr. Vaughton, it certainly cannot be to many of your readers, who once used our old friend pyro-soda, nor is it new in photographic literature. Dr. Eder pointed out the occurrence of this in "Phot. Corresp.," 1887, p. 154. Lenard and Wolff described "Lumineszenz der Pyrogallussäure," "Wiedemann's Annalen" 1888 p. 918.

Dr. Neuhauss, "Phot. Rundschau," 1895, pp. 285, 316, also described it, and said that not only the plate, but the alum bath as well became luminescent, and that the precipitation of alumina was the cause, but that it also occurred when citric acid was mixed with pyro-soda developer. Precht, "Phot. Rund.," 1895, p. 321, confirmed this observation, and showed further that the phosphorescence was entirely independent of the presence of the gelatine plate, for if dilute pyro-soda developer be mixed in a test tube with an equal quantity of 2 per cent. solution of citric acid the tube lights up and may even remain so for a minute. Von Helheim, "Photo. Archiv," July, 1896, records a series of researches on the subject, and found that a plate treated with pyro-soda containing about 1 per cent. of formaline was fogged and laid unfixed on the dark-room bench, when as soon as it was surface-dry it became phosphorescent first at the edges and gradually all over, and was so strong as to be visible even with the lamp alight.

As the developer in the dish did not show any light, Von Helheim concluded that it was due to the absorption of the liquid by the gelatine, and added an equal quantity of alcohol to the developer in the bottle, and at once the whole became strongly phosphorescent. His explanation was that the whole of the sodium carbonate was precipitated by the alcohol. Lenard and Wolff (loc. cit.) obtained phosphorescence by merely adding freshly prepared pyro solution to a saturated solution of alum, and stated that "the alumina is precipitated, and on the surfaces thus formed the pyrogallous acid is condensed, and at the same time also oxygen, and by this condensation the oxidation favoured the phosphorescence." Precht's experiment with pyro-soda and citric acid further proves that the gelatine plate is not an essential, and another experiment by Neuhauss, in which he used glass coated with plain gelatine, and obtained phosphorescence, proves that the silver salts are not necessary. Now as Von Helheim had exposed his plate in the camera and yet got

phosphorescence, it would seem that Mr. Vaughton's statement that exposure to white light destroys this peculiar property requires confirmation or confirmation.—Yours faithfully,
E. J. WALL.
January 30th, 1904.

DIAPHRAGM AND SHUTTER SCALES.

To the Editors.

Gentlemen,—I enclose herewith a diagram illustrating an arrangement of iris diaphragm and spring shutter scales devised for my own use, which, after a considerable period of trial, I feel justified in commending unreservedly to others. Although this system is a strictly decimal one, it is also approximately binary.

The area-ratio, A, for any lens and diaphragm, circular, polygonal, elliptical, or otherwise, may be defined as the number of times the effective area of the diaphragm is contained in the area of a circle whose diameter is the equivalent focal distance of the lens. As shown in the diagram, the two scales include values of the area-ratio from 1 to A-5000 (F. 1 to F. 70.7 for equivalent circular diaphragms), and times of exposure from one second to one-thousandth of a second. For any given lens, according to its capacity, the available portion of these scales may be utilised. A greater range will seldom be required, but the system is capable of indefinite extension.

The dots attached to numerals in the diagram represent cyphers, whether on the right-hand side of a significant digit, or (above the decimal point) on the left-hand side; e.g., 2, 2: and 2: signify respectively 20, 200, and 2,000; 2: 2: and 2: are .2, .02 and .002. The digit suffices, therefore, to mark any division, however great, and its small value may be. Dashes may be used instead of dots, if preferred; they are rather more conspicuous, but occupy a little more space. If the quality of an instrument is such as to warrant further refinement, all spaces between digits 1 and 2, and between 5 and 1, may be subdivided into five parts, and all spaces between 2 and 5 into parts—the latter with dividing lines alternately long and short.

Directions for making rigorously correct use of these complementary scales would be superfluous, but in many photographic operations it may be assumed that the position of any numeral upon either scale corresponds to an exposure twice as great, and any position approximately midway between numerals to an exposure one-and-one-half times as great, as that corresponding to the next larger numeral upon the diaphragm scale, or the next smaller if upon the shutter scale. For any three consecutive numerals this assumption is correct.

Diaphragm and Shutter Scales.

In two instances, and is erroneous in the third case only as five exceeds four—a difference which may frequently be disregarded. It is, to the least, likely to be long before the ordinary mechanism of diaphragms and shutters is such as to insure a much greater degree of precision. Starting, therefore, from any pair of positions on the scales for which the exposure is known to be correct, if the diaphragm opening be diminished by one or more divisions of its scale, the same exposure will be given by retarding the shutter an equal number of divisions, and vice-versa. It will be remarked that scale divisions of this system correspond to the denominations which have been adopted, for analogous reasons, in sets of metric weights.

Time and effective diaphragm-area are co-ordinate factors of exposure, and should be expressed in terms which are readily interchangeable, but the utility of this sufficiently obvious principle does not appear to be generally recognised. Upon one of the best shutters offered for sale, four consecutive divisions (not at either end of the scale) are marked 1/10 sec., 1/25 sec., 1/75 sec., and 1/100 sec. Successive ratios of difference are here 2-1/2, 3, and 1-1/3. It is perhaps to be said that shutters are seldom so well made as to justify any great pretension to accuracy in their performance. Properly that view of the subject is not altogether groundless, but if the scales attached to scales are not at least approximately truthful

they are much worse than useless, and should be omitted. We may confidently look for great improvement in shutters, for exact timing is of most importance in the shortest exposures, since objects in motion commonly require all the exposure their velocity permits. Progress in this direction is rather difficult, however, and must not be expected much in advance of an intelligent and appreciative demand for it.—Yours very truly,
JOSEPH A. ROGERS.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- F. Preece, 24A, Commercial Street, Hereford. Photograph of Organ, and Photograph of Interior of St. James' Church, Hereford.
- A. Watkins, Imperial Mills, Hereford. Photograph of a Political Post Card.
- J. Jarrett, High Street, Keynsham, Somerset. Two Photographs of Landscapes Scene, Empty Dumps, Keynsham.
- J. W. Lockwood, 13, Walfordale Place, Woodhouse Ridge, Leeds. Photograph of the Northern Union Football Cup.
- R. Easley, 35, Liverpool Road, Eccles, near Manchester. Photograph of Monton Bridge, Monton Green, near Manchester.
- J. Bates, 113, North Montrose Street, Glasgow. Five Photographs of Bands: The Royal Horse Guards (Blue), Coldstream Guards, Gordon Highlanders, Scots Guards, and the Royal Marine Light Infantry.
- F. W. Bellby, 116A, Parade, Leamington Spa. Two Photographs of the Swans at Weymouth.
- E. Charleton, Newbridge, County Kildare, Ireland. Photograph of Drummer and Drum Horse, 11th Hussars.
- J. Hudson, 60, Loampt Hill, Lewisham, London. Photograph of Craig Goch Dam Rhayader.
- J. C. H. Balmaln, 69, Shandwick Place, Edinburgh. Four Photographs of Mark Sheridan in "Cinderella," at the Royal, Edinburgh.

OPERATOR.—Not necessary.

R. E. COWAN.—Glasgow is the only address we know. We do not answer questions through the post.

COLOURED LANTERN SLIDES.—C. J. KING asks: "Where he can have lantern slides coloured by hand?" In reply: Wilkinson, Holmeside, Sunderland. See his advertisement in the JOURNAL.

COLLOIDIO-CHLORIDE PAPER.—"S. E." says: "I shall be greatly obliged if you will inform me if you think that self-toning Matt C.C. paper is as reliable in keeping qualities as any ordinary C.C.?" In reply: We should say so.

SUBSTRATUM WANTED.—T. KEYRELL asks: "Could you kindly give me a formula for a substratum to apply to celluloid for gelatine emulsion?" In reply: We should advise you to try a thin solution of plain gelatine. That will possibly answer your purpose.

SALARIES.—"HANTS" says: "I should be glad if you tell me what is about the salary paid to or amount of commission to outdoor operators in the view trade?" In reply: All will depend upon the skill and artistic ability of the operator. Such questions as this it is impossible to answer.

COPYRIGHT QUERY.—"COPYRIGHT" says: "I have a number of engravings, book illustrations, published between the years 1800 and 1880. Can I copy these and sell the photos without fear

of infringing copyright?" In reply: You will have to ascertain if there is any existing copyright in the engravings, and there is little question that there may be in some of them. Those in which there is no copyright you can, of course, reproduce without hindrance.

STUDIO QUERY.—"STUDIO" says: "I am building a new studio, 24ft. long, 12ft. wide, and 12ft. to ridge of roof. Will you tell me what length of skylight and side-light; also, how much should be covered in at end of sitters for best results?" In reply: For a studio of this length and width we should suggest that 4ft. 6in. or 5ft. at each end be covered in, and the rest be glass. Then you will have the opportunity of placing the sitters at either end as occasion may require.

OZOTYPE.—"P." asks: "Will you kindly say if you consider the Ozotype a good practical working process for professional use? Is it easily learned, and are results permanent? Does it compare favourably in these and in general respects with the regular carbon process?" In reply: The Ozotype process is easy to learn, and the results are permanent. It is very much a matter of taste as to whether the results compare favourably with the ordinary carbon process. We should recommend you to get a small supply of the necessary materials and form your opinion on the results you obtain.

BOLTING SILK.—"VULCAN" says: "In the 'British Journal Almanac,' on page 773, is an article on bolting silk to be used when making enlargements. Having many to make up to 23 x 17, I thought I would like to try the effect of the silk, but I am unable to procure it. I write to ask if you could inform me where I could get it; also the price?" In reply: Bolting silk is used by millers, and may be had of those who supply them with sieves and sifting appliances. Probably some miller in your neighbourhood would let you have what you require. We have no idea of the price.

LENS ANGLE.—"WIDE ANGLE" says: "I should be obliged if you will state the difference in distortion, if any, between a seven-inch rapid Rectilinear half-plate lens used on a half-plate, and a seven-inch wide-angle Ross Zeiss whole-plate lens used on a half-plate. I am desirous of information as to whether these two lenses both used on a half-plate would give similar distortion, and, if not, what the difference is?" In reply: With either lens there will be no distortion. As they are of the same focal length, the angle included by each will be the same when the lenses are used for the half-plate size.

COLLODIO-BROMIDE.—"M. I. DUPUY" says: "I should estimate a favour if you kindly inform me in what numbers of the BRITISH JOURNAL or what Almanacs the articles on the making and the manipulations of the collodio-bromide emulsion appeared, as I should be glad to order those books?" In reply: Formula for collodio-bromide emulsions are given on pages 1068-70 of the "Almanac." The back numbers of the JOURNAL in which articles on the subject appeared are now out of print. We should advise you to get Abney's book, "Photography with Emulsions." That will give you a good deal of information on the subject. We do not reply to correspondents by post.

STUDIO QUERY.—"H. COLLINS" writes: "I am about building a studio. The ground is only 16ft. long, if built to get a direct north light, which I intend to do. I should like your advice on the following studio: 16ft. long, 10ft. wide, 8ft. high (to eaves), 12ft. high from floor to top of studio. I intend having glass on the whole of the roof on the north side, and glass full length of eaves, having about 1ft. 6in. blocked above the floor. What I am in doubt about is, how much should be blocked, and should the glass run right to the end of studio where the sitters will sit, or should a little be blocked? Have enclosed a sketch showing what I mean." In reply: The sketch shows a very good design, but the studio will be short for professional work. We should advise you to block out about 4ft., or 4ft. 6in., both top and side, at the sitters' end.

SALARY.—"SAMOHT" says: "I shall esteem it a favour if you would let me know what wage I could draw as (1) operator, (2) operator and retoucher, (3) assistant operator and retoucher,

taking the samples herewith as my average work? Of course you must overlook any slight defects which could be obliterated by finishing off (or spotting) the mounted print. The prints enclosed have been done on "the spur of the moment," as it were, and have not had the attention which "specimens" in the true sense of the word should have; as they are chiefly intended to show pose, I think they will serve your purpose." In reply: The work, on the whole, is moderately good, but you are unable to say what salary you can command, as we do not know what is usually paid for this class of work, but probably about £2 a week in London, and less in the country.

RECOVERY OF DEBT.—"15 x 12" says: "I should be glad if you would advise me in the following matter. Some few months ago, a lady and gent called in my place and brought two cabinet photographs, from which they ordered some Christmas cards, and 15 x 12 bromide enlargement off one. I did not ask for a deposit, as I thought they were all right, and, more so, as a week after they called and paid for the Christmas cards, and asked me to try to get the enlargement through to Christmas. This I did not definitely promise, as I was very busy; but I did get it through, six days before Christmas, only being ordered ten days prior to this. I wrote to say I was ready, but received no reply. I saw the gent. a few days later, and he said he would call for it the next day, and, as he had had it in my window, he had seen it, and said it was splendid. However, he has not been for it; and I have written him again, but with no effect. Can I take any steps to compel him to have it, or what should you advise?" In reply: We should say that the best way will be to send the picture home and if it is not paid for sue for the money in the County Court. We don't see what else can be done.

SINOP.—"TROUBLED" says: "I have bought a Sinop outfit, which I claimed to do good collotype work, and at present (after spending about two dozen plates) in my hands is useless. Kindly say (1) have you seen any work done by that process, and if you consider it possible to turn out good collotype post-cards with that outfit? (2) Where can I get a good book on collotype work? (3) Who supplies machinery and necessary tools for collotype work? (4) What are photo mechanical processes used for? What particular part do they take, and what advantage have they over the ordinary? (5) I think of dealing in photographic materials, chemicals, etc. Kindly say what I can get a schedule of poisons, etc., so that I can know what to can and what I cannot sell without running in danger with the Pharmaceutical Society?" In reply: (1) Yes; certainly. (2) "Practical Collotype," by A. W. Fithian. It may be had through any of the dealers. (3) Messrs. Penrose and Co., 15, Finsbury Road, E.C. (4) The plates are made specially to give extra density and clearer shadows than are yielded by most rapid plates. (5) The schedule of poisons will be found on page 1002 of the "Almanac."

* * We are again obliged, through exceptional pressure on our space, to hold over many reviews, notices of new apparatus, answers to correspondents, and several articles, including one on "The Elimination of Hypo by Means of Barium Chloride."

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Professor Abbe. It will be welcome news to the optician, students of the microscope, and many who are merely interested in the social development of the town of Jena, to learn that a collection of the treatises and addresses by Professor Abbe is in course of preparation. The idea was conceived by Dr. S. Czapski some years ago, but although a beginning was then made by him, the pressure of other duties prevented further progress until the co-operation of some of the younger members of the scientific staff of the Carl Zeiss Works was obtained. The first volume has just been published. It contains a collection of twenty-two papers relating to the theory of the microscope. Typographically the volume is worthy of the text. A portrait of the author constitutes the frontispiece. Of these twenty-two papers no less than nine appeared originally in the Journal of the Royal Microscopical Society. It is characteristic of Professor Abbe's scientific cosmopolitanism that these papers were written in English for an English scientific society, and that it has been necessary to translate them into German for the purpose of this publication. We venture to make the suggestion, that the Royal Microscopical Society should obtain permission to translate the German papers, and publish for the benefit of English students of the microscope the whole collection contained in this volume. It could be a worthy recognition of the valuable work Professor Abbe has done in this branch of optics. The

sympathetic remark, in the preface, by Dr. Czapski, that the collection has been made without the knowledge of the author during his recent illness, will find a warm response in the heart of everyone to whom the name of Abbe is familiar, and we trust the time may not be far distant when he will again enjoy his old capacity for scientific work.

* * *

Celestial Photography. It will be remembered that about fifteen years ago an international congress met at Paris, under the presidency of Admiral Mouchez, to consider the practicability of obtaining by photography a survey of the entire surface of heavens. It was a stupendous undertaking, but it was decided upon, and the necessary conditions were arranged. Plates of uniform size were to be exposed on different sections of the sky by various observatories all over the world, and the work must now be approaching completion. But those who might think that the enterprise has been too long in progress have very little idea of the difficulties involved. The weather of 1903 has been a stumbling-block to the astronomers of Britain, as it has proved to be to nearly all the other subjects of His Majesty. It seems hardly credible that out of a possible two thousand hours or thereabouts, only fifty-two were suitable last year for celestial photography. Possibly users of the camera for its more ordinary work who consider that they have ample grounds for abusing the weather, will feel that the astronomers have still better reason to grumble. In regarding these figures it must be remembered that moonlight nights as well as clouded ones are barred for photographs of the stars. It is for this reason that we place the possible number of hours as low as two thousand. This photographic charting of the heavens is the grandest astronomical scheme which has ever been undertaken, and it aims at securing an accurate map containing two million of the brightest orbs. This is not much more than one per cent. of the stars which possibly could be photographed by extremely long exposures, exposures which would secure images of those distant bodies which the eye has never seen, even when aided by the most powerful telescope. But the two million will be sufficient to afford direction posts which will, it is believed, help in the solution of many abstruse problems. One of these relates to the journey of our solar system through space. It is known that our sun, with its system of planets, is rapidly moving among the stars at a rate of several miles per second; but this is all which is at present vouchsafed to us. We have no idea as to whence we have come, or as to whither we are bound, and we can never know except by such information as a true chart of the universe may be able to afford. In the making of this chart the chief obser-

vatories of the world are taking part, but it could not be done without the potent aid of the photographic plate.

* * *

A New Colour Scheme.

When the prophet Jeremiah asked "Can the Ethiopian change his skin?" he no doubt thought that he had hit upon an unanswerable conundrum; and he little thought that in the twentieth century a man would be so bold as to dare to answer it in the affirmative. The man is a certain Dr. J. W. Hill, of Indiana, and he proposes to prevent infants born of negro parents from reverting to the old condition of things, so far as their skins are concerned. And it is all to be done, just as you would develop a photograph, by red light. We know that red light has proved valuable in the treatment of small-pox; but surely a more curious use for dark-room illumination was never thought of than that to be presently adopted by Dr. Hill. First we learn "that an expectant negro mother has consented to act as patient." It has been written that those persons who expect nothing are especially blessed in not being liable to disappointment, and we sincerely hope that this negro lady does not expect too much from this experiment. She is to remain in a room furnished in red, lighted by red, and will be ministered to by physicians and nurses dressed in red. We should have thought, in our sweet photographic simplicity, that red light would have been sufficient without all this dressing-up, but the Indiana doctor evidently wants to do the thing thoroughly. He is going to pull the leg of Jeremiah or he will know the reason why. His theory seems to rest upon the assumption that the negro's skin in particularly sensitive, more sensitive, he asserts, than that of any other human being. And that for this reason Nature has provided it with a pigment which will enable its owner to withstand the intense heat of the sun in those portions of the world from which the negro race originally sprang. Now a negro child is generally born white—again we quote from Dr. Hill; we do not assert this of our own knowledge—and it turns darker under the action of sunlight. Dr. Hill, in fact, seems to believe that the negro skin is like an unexposed chloride of silver surface—keep it under red light, and it will not turn black. It is not stated how long the baby is to be kept under this protection, but we might suggest that before it is allowed to make acquaintance with the unfiltered light of day, it might, as a precautionary measure, be dipped into a bath of strong hypo. We do not know whether this valuable suggestion has occurred to Dr. Hill, but we present him with the idea. His experiment is a most interesting one, but we might venture to remark that negro women have been known to give birth to white children before now, without any help from ruby light.

* * *

The Theory of Photographic Processes.

Such is the title under which Dr. Lüppe-Cramer gives in the "Photographische Mitteilungen" a resumé of his work upon the subject since the close of 1902. He thinks it is established that the alteration of the silver haloids by exposure to light is not of a simple nature. Chloride, chloro-bromide, and unripened bromide plates may be physically developed after fixing, even if the exposure is normal, as for ordinary development. But if such plates are treated with solvents of silver, after fixing, they can no longer be developed, which is proof that traces of silver must remain in the film. These traces of silver entitle us to infer that exposure causes a chemical change. Extra rapid plates differ. They require much longer exposure for physical development, from which Dr. Lüppe-

Cramer infers that exposure causes molecular change at an earlier stage than liberation of bromine. The high sensitiveness of bromide of silver depends upon ripening wherein lies its greater usefulness. Chloride changes quicker visually by exposure, and it is more susceptible to development, if ripening be excluded. Digestion and action of silver solvents produce exceptional sensitiveness of bromide, but although chloride acquires increased sensitiveness in ripening, fog is produced at an early stage and satisfactory results are no longer obtainable. The microscope reveals that fog may be assigned to isolated particles, and that every sensitive particle of silver bromide does not contain a minimal nucleus of reduction. Some far-reaching experiments by the author with mercuric iodide emulsion point to the fact that the colloidal medium also plays a part, and it cannot be denied that modifications occur in the ripening process. The difference between collodion and gelatine emulsion was for a long time ascribed to the sensitising action of the latter medium, but experiments have shown such is not the case. It is probable that the process of ripening does not proceed in alcohol as it does in aqueous solutions of gelatine. Solarisation still remains unexplained. Abney's theory of oxidation was accepted for many years, but the fact that solarisation takes place in the absence of oxygen, and that the substance of the solarised image differs from the normal quantitatively, instead of qualitatively, deprives the theory of any foundation. An hypothesis of less general acceptance is, that solarisation is caused by the tanning action of bromine on the film, but it is excluded by the fact that solarisation occurs in the collodion and daguerreotype processes. Photographic processes contain many enigmas and it must be admitted that practice and theory do not proceed hand in hand. The investigator is not only hindered by the microscopic nature of the chemical processes, but by the endeavours which are made to set up hypotheses prematurely on the strength of isolated observations. These often in the course of years acquire the sacred character of dogma.

* * *

Phantasmagoria.

This word, which is now almost obsolete, was familiar enough to our fathers. It is defined in Nuttall's Dictionary as "Representations made, as by a magic lantern." A few decades ago, before photography had turned the nursery toy into an extremely valuable scientific demonstrator, there was a distinction between a magic lantern and a phantasmagoria lantern, the latter running on a kind of trail line so that the image of any ghost, hobgoblin, or other uncanny creation of the slide-painter's art might be made to wax or wane upon the sheet or screen provided for its reception. There are probably few persons in a civilised community who would be frightened by any manifestation of this kind; but it was not so in a more ignorant age, and a quotation from the "Times" of one hundred years ago will show. We will not give the extract verbatim, for it is too long; but we are informed that on a certain night in January, 1804, one of the Coldstream Guards, on duty at St. James's Park, saw the figure of a woman without a head rise from the earth close to him. He described the dress minutely, and says that the figure was enveloped in a cloud. "In about the space of two seconds, while my eyes were fixed on the object, it vanished from my sight. I was perfectly sober and collected at the time, and, being in great trepidation, called to the next sentinel who met me about half-way, and to whom I communicated the strange sight I had seen." Another soldier gave a solemn declaration much to the same effect, and the "Times" evidently gave full credence to the statement.

However, certain other papers seem to have charged the "Times" with having fabricated the story, and to this gives, in a subsequent issue, an indignant denial. It is evident that the alleged appearance of this headless ghost in such a public place as St. James's Park made an immense sensation, and a good clergyman "entered the Bird Cage Walk, and patrolled it for several hours, in the hope that he might meet the figure, when, he trusted, he should detect some person, who, through wantonness, was endeavouring to alarm the neighbourhood." But this midnight vigil had no result whatever. The ghost who was not afraid of armed men refused to tackle the parson, and so things remained unexplained for a week, when a small paragraph appears in the "Times," which laid the ghost to rest for ever. "The ghost in St. James's Park, we understand, originated in an application of the phantasmagoria, by two unlucky Westminster scholars, who, having got possession of an empty house on the side of Bird Cage Walk, were enabled to produce the appearance which so greatly alarmed the sentinels on duty in the immediate vicinity of the spot, and has given such an extraordinary subject to the curiosity of the public." Those who can look back upon the escapades of their repressible boyhood with pleasure must feel a pang of regret that they could not have shared the intense joy of those two Westminster scholars, who set the whole of London by the ears with their pranks. There is not so much fun in the world now that magic lanterns and such familiar things. And as to ghosts, they seem to have forsaken us altogether; we do not even get any spirit photographs now. The episode in St. James's Park, with the ghost and the sentinels, recalls to the mind the first scene in Hamlet, but with a decidedly comic dénouement.

THE OLD PHOTOGRAPHY AND THE NEW.

In concluding the article in our issue of the 22nd ult., which the question was mooted as to whether photography, as regards the stability of its results, is progressing, considering prints that were made several decades ago, we intimated that we might recur to the subject, and point out the differences in the condition of working then and now. Many who have only entered the ranks of the photographer since the introduction of gelatine photography have a faint idea of the processes that were in vogue before that period, and the wide difference there is in the principles involved in their working. Take, for example, negatives. The light sensitive salt is quite different, the principle of development was different, and the fixing agent is also different. We, of course, are, for the moment, referring to the wet collodion process.

With the wet collodion process the sensitive salt is a mixture of silver plus a very small proportion of the bromide. With gelatine plates it is bromide of silver plus (generally) a very small proportion of iodide. In the collodion process an iodide—say, of ammonium or cadmium, or both—is dissolved in the collodion. This, by immersion in a solution of nitrate of silver, is, by double decomposition, converted into iodide of silver in the plate. The plate, when taken out of this bath, is exposed in the camera with the free nitrate of silver, both on the film and on its surface. The developer, instead of being alkaline, as with gelatine plates, is strongly acidified; and its action, after exposure, is to reduce the silver present to the metallic state, and deposit it where the light has acted. After the image is brought out by the acidified iron developer it is intensified with an iron pyrogallol solution to which more nitrate of silver

has been added, the intensification being merely the deposition of more silver on the image. Hence we have in the finished negative the image consisting of metallic silver embedded in a quite inert material, as the collodion forms no compound with the silver. The fixing agent is also different from what is used for gelatine plates, cyanide of potassium being what is almost universally employed in the collodion process, hypo being but very rarely used. The cyanide of potassium and the cyanide of silver formed, are very soluble salts, and have no affinity for collodion; consequently they are quickly removed from the exceedingly thin film, with two or three minutes' washing under the tap. When finished, collodion negatives are always varnished—indeed, they cannot be printed from before without great risk of their being ruined by abrasion of the film.

Let us now consider the gelatine process. Here the sensitive agent is the bromide, and not the iodide of silver. The bromide of silver is formed in the emulsion, and there is no free nitrate of silver in the film. The developer is an alkaline one, and its action is to reduce the silver in the bromide to the metallic state in proportion to the light's action. There is no deposition of silver from what may be termed outside sources, as in the case of the collodion process. The image is formed entirely of the silver reduced from the bromide. The fixing agent here is always hypo, and, by reason of the great thickness of the gelatine film, as compared with the collodion one, its action is much slower and also after fixation the negative requires a much longer washing to remove the last traces of the hyposulphite and the hypo silver salts than is the case with collodion. Again, by far the larger proportion of the gelatine negatives now produced are not varnished at all; consequently when they are dealt with under adverse conditions—such as being stored in a damp place, or printed from in contact with damp paper—they frequently suffer serious deterioration.

Prior to the invention of the collodion process the negatives were on paper, or on albumenised plates. But with them the same principle obtained as in the collodion process. In the case of the calotype process, for example, the paper was prepared with an iodide, such as that of potassium, and dried. It was then sensitised with an acid solution of nitrate of silver, containing a reducing agent, gallic acid, and iodide of silver was formed in the paper. This was exposed wet, as with collodion. The action of the developer was to reduce the silver in the free nitrate to the metallic state in the parts acted upon by the light. In the waxed paper process, after the paper had been sensitised, the free nitrate was washed away, but it had to be restored for the development of the image.

In the albumen process the conditions are similar to those obtaining in the wax-paper process. The albumen was iodised with a potassium or ammonium iodide, dried, and then sensitised in an acid bath of nitrate of silver, when the iodide of silver was formed by double decomposition. The free nitrate was then washed away and the plate dried. After exposure the image was developed with an acid developer containing nitrate of silver which was reduced and deposited in proportion to the light's action, as in the processes just referred to. The fixing agent in all these processes was hypo, and in the last-named, by reason of the thinness of the film, it was easy of removal. But in the case of paper negatives it was different, and more care was necessary, and it was usually bestowed upon them. This was the method usually followed. When the negative was taken from the fixing-bath, it was carefully pressed between blotting-

paper to remove as much as possible of the solution. It was then soaked in water, and washed under the tap for a time, and again blotted off. These operations were repeated until it was judged that the paper was freed from the hypo. In this way the last traces of it were effectually removed in a comparatively short time. Calotype negatives, it should be mentioned, used to be waxed before they were printed from, and that was practically equivalent to varnishing them.

We have here in simple language, without going into the chemistry of the subject, explained for the benefit of those who are not familiar with the theoretical part of photography the difference in the principle involved in the processes in vogue prior to gelatine photography and wherein it differs. We had intended to have dealt with positive processes as well, but space will not permit in this article.

RANDOM THOUGHTS ON EXHIBITIONS AND EXHIBITORS.

By THE AMATEUR OPTICIAN.

ALTHOUGH I have not ceased to take photographs, nor abated any of my early zeal for the art—excepting only the physical discomfort of carrying heavy apparatus—it is fourteen years since a frame of mine appeared in competition at any exhibition of photographs. I have a frame of medals, some of which I feel reasonably proud of, and one or two of them I never look at with any degree of pleasure because of the circumstances surrounding their bestowal. I do not suggest, of course, that there was any deliberate “hanky-panky” about the business—the particular judge here was a noted man, above suspicion, and has been off the mortal sphere some years—for all that, there was, to my mind, and others, I think, must have thought the same, an element of absurdity about certain awards; whether traceable to the hard and fast rules and classes laid down and fixed, and, as a natural consequence, the somewhat restraining influence on the judge, this I cannot say positively; the one obvious fact remains that there were pictures shown on this occasion—the class not being considered—to which I would gladly have yielded up my medal.

It is ordinarily said in reference to various matters that “lookers-on see most of the game.” This applies, in a very small way only, to exhibitions, in the case of which those behind the scenes are nolens volens often made cognisant of, or participators in, incidents calculated to cause a feeling of discomfort, if not to actually raise a blush. My firm conviction is that the system of classifying exhibits is a pernicious one; also, that the appearance of officials in the competitive arena is a great mistake. The contrariness of human nature is a point one need not discuss here; enough to say that men have been known to go to strange lengths for the sake of a medal, which, awarded or given under such circumstances, can surely convey no satisfaction whatever.

I had rather a curious experience on one occasion bearing somewhat on this particular point. A certain exhibition was in view, and a customer of mine was one of the organising secretaries; he put in a lot of hard work over this, so much so that within a fortnight of the opening of the show he had nothing of his own ready for hanging—as a fact, he had not even exposed any plates; however, there was one weekly holiday intervening, and it was a case of now or never, whatever happened in the way of weather—wet, shine, or fog—the thing must be done if the medal in view was to be got. Well, this gentleman bought some plates of me, borrowed a whole-plate camera from the same party, and went off to expose his plates. Now, what the identical pictures were I cannot remember, but I know that he pulled off the medal, which was, to say the least, an unique piece of work.

The same gentleman subsequently informed me, quite gratuitously, that “I had spoilt my chances because of the frames”; this was in allusion to a few rather successful things (elsewhere) I had sent in, just as received from a previous exhibition. What has always been a puzzle to me is what framing had to do with it? Secondly, how he came to know this momentous decision of the judges, and what, anyway, business it was of his?

Your correspondent in the JOURNAL of the 15th of January has evidently been stirred by some vagary in the way of judging. “Give credit where it is due” may be all very correct as an abstract proposition, but we must not be too particular. Some persons prefer the other old saying, “You scratch my back, I’ll scratch yours.” I do not intend to imply that our judging at the present time is unfair, though it is often manifestly incomprehensible; the gross and palpable mistakes, if made, are the natural result of putting men who are known to hold extreme opinions, if not actually exponents of a cult, into a position which, above all, requires an evenly-balanced mind, not strongly inclined to one side or the other. I have known more than one quite estimable young fellow to be inordinately puffed up by elevation to the bench of judges, and so conceited thereby, as to be positively insufferable.

Our friend has probably concluded that the mere photograph is only one part of the business. There are judges apparently who have acquired a great dislike to certain bits of English landscape. I once had a letter from a secretary in this strain: “It’s no use sending photographs of —, and —, and —, and — on. We are sick to death of them, and they stand no chance! Now, how is the innocent and well-meaning exhibitor to know anything about this strong feeling which, likely enough, exists in some quarters to-day?”

Apart from these little pitfalls, the method of printing is to be gravely discussed; indeed, this is probably the most important part of the whole intricate business, of vast importance and not to be lightly considered or put on one side as a frivolous import. One may say at once that a nice, clean, and healthy-looking platinum or bromide print is severely handicapped from the start, while a vulgar P.O.P., matt., or otherwise, is out of the running altogether; in fact, cleanliness and technique generally—one may almost add, newness—count for very little, as our correspondent clearly anticipates. Something may, however, be done at times with an over-exposed bromide, or one rather thin and yellow; in the case of the former, a good plan is to develop the print with a minimum solution, applying it with a camel-hair brush; if, now, we arrange for a few splashes of hypo—or a piece of sunlight suddenly dropped in will do at a pinch—we may, perchance, obtain some striking effect of light and shade which will not fail to appeal to some judges. But, of course, the process par excellence “gum-bichromate.” In this case the negative is a detail of no great significance. I am assured that the expert “gum” man can produce a portrait study, a landscape, or seascape from one negative; it all depends upon how much sawdust you rub into it; this is a matter I do not vouch for.

As for mounting and framing, the exhibitor must move slowly and tentatively. The print should be trimmed with scissors; a straight edge is an abomination, as also is a straight edge. The mount itself is a serious concern; coarse brown paper seems to be popular and effective, though there are possibilities. The direction of sugar paper one could not make a grocer-mean, grosser mistake than to neglect such artistic colours are obtainable from such a source. With regard to framing, it may be said at once, and without fear of contradiction, that no amount of time, labour, or money spent upon a mere frame will affect the judges to any extent worth mentioning, always supposing that the object in view is the annexation of a medal. In one sense this is as it should be, and I have already made mention of a little personal experience bearing upon the matter.

on the other hand, it may be truthfully set down that a neglect of the proprieties in the matter of framing in any way acts against the exhibitor, but is rather in his favour; gems of art as we have been thinking and talking of are no elaborate setting. Our correspondent's remarks with regard to "carelessness," "air-bells on the surface," "uneven development in the shadows," etc., are really harsh and crude. The highest form of art is to conceal art—and we are told it is so—the author or perpetrator of the work referred to doubt had all this in view as part of his "colour scheme"! Bells, forsooth! These are, without doubt, intended for flowers. But, apart from that, I say at once that a man can put in a good air-bell, and simulate what our friendly terms uneven development, is no Snifter! With regard to such artists as I have quite inadequately referred to, it is professional only who has a chance on rare occasions of turning his own back, so to speak. Now and then we meet with one of these soi-disant artists and medal-hunters who takes a little of his own; he will probably sink his own name, and come forth as, say, "Solazzi et Cie."; but if he wants to get out of the Official Receiver's hands he takes care to select some competent man on the premises to do the work and please the public. More often he condescends to do the work for a professional, with dire results to both parties. The situation usually is of the nature pathetically described by our correspondent. One passable print out of twenty is a average, I believe, or one lantern-slide in twelve; but the variety of tone complained of is obviously not a mere accident, but a studied effort of genius.

It is an unexpressed but common consent, the subject of the war, in the case of our brother Boer, is rarely referred to now, and the affair would not have cropped up here but for the reason that an old customer of mine has just been informed that I have not seen (but often thought about) for three years or so, at a time when the iniquities of the War Office are popular subjects for casual talk. I remember the time distinctly, because the familiar topic came up as usual, and eventually I said something about "red tape." "Ah," said he in a slow, exasperating way, "I've often heard of that red tape, but I've never seen any!" It is curious how one drops the track of this class of ignorant person in unexpected places. A business friend of mine is a manufacturer on the small scale, and a man of note locally, has a strong political leaning and has more than once "put up for" guardians and councillors—therefore presumably a man with some knowledge of affairs of any rate, I gave him credit for so much. Well, we were sitting together a short distance. I called his attention as a man to a strong speech by Sir John Gorst in the day's paper. I thought would please him. He read it through carefully and with evident appreciation, then said, "Who is he?" I said not often that speech fails me, but this kind of person I never over quite.

I started about the late war because, rummaging about, I found up a photo of a friend who, being on the Reserve, was called upon to serve. I must say that, in total ignorance of what was in store, we did the thing very handsomely—presented him with revolver and field-glasses—fit for a Field-Marshal—and sundries generally enough to make a happy man for a year or two; and he was, of course, photographed at a rig in the midst of all the paraphernalia. Handling the photograph reminded me of the sequel: how he was detained at a dépôt for some weeks prior to starting for the front. How these presents got to be little better than a nuisance; how one or other of them got lost, strayed, or stolen, and arrived at his destination, he was rather worse off than when he started; and, finally, how on his return I and two or three friends met him, and shook him carefully by the hand—carefully, because he came decidedly within the meaning of a clause of the Act of Parliament which I need not further specify.

We had arranged to preserve the clothes he stood in as a memento of a glorious campaign, but it was thought best to burn them *instantly*. The next time he goes to the wars we have decided to drop the revolver and spy-glass business, and present him instead with a seven-pound tin of *Unguentum Hydrargyri mitius*—i.e., the rightly-named troopers' ointment of the unofficial pharmacopœia, as being more to the point! *Sic transit gloria belli*.

FIFTY YEARS AGO.

[From the *Liverpool Photographic Journal* (now *THE BRITISH JOURNAL OF PHOTOGRAPHY*), of February 11th, 1854.]

WE have the gratification of recording that our first efforts have been greeted with a kindly welcome from all parts of the Kingdom of Great Britain, and a friendly hand has also been extended to us from Ireland. In addition to the report of the last meeting of the Liverpool Photographic Society, we are able to redeem our promise of giving an extensive notice of the London Photographic Exhibition, which is of such a character as we hope will stimulate our local photographers to great exertions on behalf of the exhibition proposed to take place here in the autumn. It will be seen by our advertising columns that Dundee will, in point of time, take precedence of us, as the Committee of Management—which includes Lord Kinnaird, Sir David Brewster, and all the leading people of the neighbourhood—have resolved to open in the middle of March next, and continue the exhibition into the middle of April; the proceeds, after the payment of expenses, to be handed over to the Dundee Royal Infirmary. They invite and solicit the loan of specimens from the members of the Liverpool Photographic Society and elsewhere, and they have our good wishes in the course they are adopting. At Plymouth there has been a great gathering of the Devon and Cornwall Photographic Society. Everything concurs to arouse the energies of the members of the Liverpool Photographic Society, to enable them to hold a prominent position in the art when they will be subjected to the criticism of the British Association. The weather has not been favourable for photographers of the moon, but some few experiments, we hear, have been made with tolerable success.

ECONOMICS IN PHOTOGRAPHY.

No. 1.

SILVER.—It is recommended in most manuals to soak the paper positives in distilled water before fixing in the hyposulphite bath. We may go a step further, and (where the photographs are large) save a considerable portion of the silver used, by the following process:—Save the water in which the proofs have been washed, and after putting in a few drops of nitric acid, to neutralise any ammonia in excess, pour in a solution of common salt; stir well together, and allow the white precipitate of chloride of silver to subside; the water may then be poured away, and the chloride washed out into a basin, or other small vessel, and put aside. This process being followed continually, the quantity of chloride of silver collected will soon become very considerable, and when in sufficient quantity to render a reduction to the metallic state advisable, that operation may be performed, and metallic silver of almost absolute purity is produced, which may be dissolved in nitric acid and converted once more into nitrate of silver.

DIOGENES.

TECHNOLOGY.—The absence of a compendious Glossary of the Technicalities used in Photographic works has been so much felt by amateurs, and especially by those who have just commenced their noviciate in the fascinating study, that we have decided upon devoting at least one column monthly—more, should space permit—to supply this desideratum. This work has been entrusted to one of the members of the Society, who will, where necessary, be assisted by the experience and opinions of others; and no pains will be spared to make it worthy of

the attention of all. It will not be a mere dry dictionary, but will be interspersed with numerous remarks, hints, and cautions of the utmost service to beginners, and perhaps not unwelcome to more advanced practitioners. We propose to divide it into four sections:—

First.—Of Terms as applied to Processes. These will be arranged as nearly as possible in the order of their discovery, without regard to alphabetical arrangement. The minutiae of each process will not be entered into, as that would be unnecessary; but merely the general distinctive marks, and the discoverers', names will be given.

Second.—Of Technical Terms as applied to Apparatus.

Third.—As applied to Manipulation.

Fourth.—As applied to the Chemicals employed.

Each of the three last sections will be separately alphabetically arranged.

For the benefit of those who have the opportunity of reading French works on photography, but who find neither their own knowledge nor their dictionaries any assistance in elucidating the new nomenclature introduced by recent discoveries, the French terms will, wherever practicable, be introduced after the English, and printed in italics, to catch the eye more readily.

In the chemical section, besides the English and French names every name each substance is usually known by will be given; together with a general indication of its uses in photography, and in all instances where there is any risk attending the use of a chemical, whether from being poisonous in itself or in its combinations, these points will be noticed.

Accordingly, we will present a portion of the first section in our next sheet.

DEVON AND CORNWALL PHOTOGRAPHIC SOCIETY. — A very interesting meeting—the first meeting—of this Society took place in St. George's Hall, Stonehouse, at which a great number of specimens of the various styles of photography and daguerreotype, with stereoscopes, microscopes, and photographic apparatus, were exhibited, and some photographs taken in the presence of the company by artificial light. The meeting was attended by all the most distinguished people in the neighbourhood, and gave great satisfaction to all who were able to be present. We intended giving a full report of the proceedings, but an extra pressure of matter compels us to be brief. Capt. R. E. Scott, the President of the Society, concluded the evening with a very admirable speech on photography.

PHOTOGRAPHS OF THE MOON. — We understand that Dr. Edwards and Mr. J. A. Forrest are engaged with Mr. Hartnupp, at the Royal Observatory, in attempting to obtain photographs of the moon. In connection with the subject, we may refer such of our readers as take any interest in it to an article in the *Dublin University Magazine* of this month, on "The Lunar World and its Wonders, of which, if our space would have admitted, we intended giving a short abstract. At present can only say that it fixes 500 as the highest power that can be applied with advantage in obtaining photographs of the moon, any higher power tending to distortion of form or indistinctness of detail.

THE EXHIBITION OF PHOTOGRAPHS AND DAGUERREOTYPES, BY THE LONDON PHOTOGRAPHIC SOCIETY.

We are enabled to give an original critique on the exhibition of photographs, in London, by one of our own members, who has very recently visited it.

The number of photographs, of all kinds, from the daguerreotype to collodion, wax-paper, albumen, etc., nearly reaches one thousand specimens. These fill the large room of the gallery in Suffolk Street, as well as two small rooms at the south end. The centre of the large room is occupied by a number of stereo-

scopes of both kinds—the common form, and that of Mr. Wheatstone; specimens of exceedingly minute copies of prints on papers, with microscope to view them, sent by Mr. A. Rosling; daguerreotypes and calotypes, by Mr. Mayall; photographs by Mr. A. Rosling; a negative photograph by Mr. Sanford, taken on 19th December, 1851; etchings, by George Cruikshank; Bartholomew, on glass, covered with collodion and guttapercha, and printed by P. W. Fry, also on the 19th December, 1851; the first protonitrate positive upon glass, by Dr. Diamond; three stereoscopic pictures, taken from the actual head of Henry Grey, Duke of Suffolk (the father of Lady Jane Grey), who was beheaded in 1554; in which No. 2 shows the incision made by the first cut of the axe, the executioner having failed severing the head at that blow, and requiring a second stroke for that purpose; the head has been preserved in a tanned state by the antiseptic properties of the vault in which it was deposited, at the Church of Holy Trinity, Minorities, near the Tower of London. There are collodion positives, by Mr. Ripplingham. Five portraits, collodion positives, by C. Richardson; nine stereoscopic collodion positives, by Stewart; a view of Solent, from Osborne, Isle of Wight, on collodion, by J. Becker, showing the natural impression of clouds; a daguerreotype of a snow scene, by R. Lowe; a series of photographs, illustrating the various tints acquired by a shorter or longer exposure in the old hyposulphite of soda bath, by T. Williams, and some prints from steel plates, which have been etched by the bitumen process of M. Niepce, by Bisson, exhibited by Mr. Solomon.

These are arranged on screens and stands. From end to end the walls are covered with photographs, indiscriminately mingled, rather with a view to the general effect of the exhibition than to scientific classification, or experimental comparison of the various methods employed. The most striking example on entering the room is a very large calotype, from a negative on iodised paper, by E. Baldus, a view of the Amphitheatre at Nismes. It is about three feet six inches long, perfect in perspective, rather reddish in tone, but very minute in detail, and altogether a very favourable example of the power to produce representations on a large scale by photography. It is probably enlarged from a smaller view, taken by means of a camera, but the catalogue does not give us any information of the subject. There are three or four large copies of busts, of them life-size, by Counsellor Auer, exhibited by the Photographic Society, which are also very favourable instances of the capabilities of photography to produce works of large size, though we cannot think that the subjects in the last-mentioned examples are such as to do justice to the peculiar advantages afforded by the photographic art. Counsellor Auer's are fine negatives on wax-paper, the tints very solid and even in quality, too much so, indeed, to afford the brilliancy that is required for such large work. The painters find as they increase in work in size they are obliged to open the texture of the execution, or the shadows will become heavy, and the mid-tints rapid or dirty, as they may be light or dark.

There are a number of copies of engravings of various degrees of merit, by P. Delessert and Mr. Aguado, some from negatives on wax-paper, some from collodion, others from the talbotype, which in these instances appear to have been the most successful. There is a beautiful copy of a crayon drawing, by Richmond, printed from a negative or collodion, by C. Thompson; Mr. James Contencin has also been successful in applying the same process to the same purpose, but we cannot speak so favourably of his copies of pictures. Sir Thomas M. Wilson has been more successful in his calotype and talbotype copies of pictures by McIan. There is a very good copy by Bisson Brothers, of the Hundred Guilder print, from Rembrandt's etchings, so called, because a single impression of the original was sold for that sum; but by what process a copy is produced is not mentioned. Mr. F. Bedford exhibited

copies of the lithographic prints, from Roberts's sketches the Holy Land; but, except as trial of skill, these cannot be considered an advisable proceeding in photography. Copies of rare or valuable engravings, such as the Hundred Guilder print and the Annunciation to the Shepherds by Bisson, on collodion, also from Rembrandt, are very legitimate exercises in the art; but not such works as are existing on stones or plates, and capable of being produced in a direct way as perfectly by another process. The substitution should be for the purpose of skill in copying on to the stone or plate, not for the purpose of that stone or plate, where the labour of placing there has been undergone. The object of the photograph from an original drawing, as in Mr. C. T. Thompson's beautiful reproduction of Mr. Richmond's head, is to avert the risk of error in copying, by the lithographic draughtsman or the engraver. If they have been successful, the photographic copy of their work will not be superior to the original; if they have made any error, or failed in any part, the photographic copy will not remedy or remove them. On the other hand, in this substitution, there are some beautiful specimens of photolithography of architecture, by Mr. Lesecq, from wax-paper negatives, and of the stained glass windows in Cologne Cathedral, Marable, on the same method; and of photographic engraving on steel, of objects of natural history, from collodion negatives, by Bisson Brothers, which are exquisite in detail completeness, and obviating the possibility of mistake or error, form the most legitimate and most valuable exercise of photographic art.

Mr. Fox Talbot exhibits some beautiful specimens of engraving on steel plates, by the influence of sunshine, on a preparation of chromium and subsequent etching by chloride of ammonium.

The Rev. W. J. Kingsley and Counsellor Auer exhibit some remarkable examples of the application of photography to the microscope, from negatives or wax-paper; and we think we have some reproductions of similar microscopic objects by the electro-chalographic process, than which nothing could be a more perfect application of photographic art, as human eyes and hands can scarcely be minute enough, and certainly cannot be adequately remunerated for the work, if they have the opportunity to prepare it. In one instance the Rev. W. J. Kingsley has been very successful in obtaining photographs of microscopic objects, by artificial light, on wax-paper negatives.

Mr. C. T. Thompson and Mr. F. Bedford have applied the photographic process very satisfactorily, in general, to still life, objects of furniture, plate, and vertu, which are never worth the time and talents of an artist upon to produce the accuracy that usually constitutes their chief value.

Comte de Montizon has devoted his operations in the photographic process to the equally legitimate and valuable, though more difficult, task of fixing indisputable representations of objects of natural history, at the Zoological Gardens, Regent's Park, London. The backgrounds sometimes interfere with these otherwise admirable specimens of photography, as they do with science and the embodiment of truth.

The photographic reports of the engineering commissions in Russia, by Mr. C. Vignoles, taken by Mr. Roger Fenton, and of the progress of the Crystal Palace, at Sydenham, by Mr. C. Delamotte, exhibit another highly valuable application of photographic art as preserving an indisputable record of facts.

William Crookes—to whom the art is indebted for a very important process on waxed paper, and the means of restoring degraded collodion, referred to in our last number—exhibits the results of some experiments on light by means of photography, which may be of great importance. He first gives a photograph of the solar spectrum; then the effect produced by exposing the spectrum on a sensitive surface of iodide of silver, and developing.

"The action is due only to the indigo, violet, and invisible rays; no effect taking place where the red, orange, yellow, green, or blue rays fall."

3. The effect produced on bromide of silver under the same circumstances.

"The action is here due to the upper three-fourths of the green, together with the blue, indigo, violet, and invisible rays; no action being produced by the red, orange, yellow, or lower part of the green."

4 and 5. Photographs of the solar spectrum after having submitted it to the absorbing action of sulphate of quinine.

"The only rays which this substance allows to pass are those below the violet, limiting the photographic action, in the case of iodide of silver, to a narrow band about the centre of the indigo; and in the case of bromide of silver to the upper portion of the green, the blue, and indigo rays."

These results deserve the serious consideration of the scientific photographer, as they appear to involve a partial action of light that may account for many of the failures we find in the most successful operations, and some means may be discovered whereby the action of the light may be made more uniform; for, until that is done, it will be hopeless to make the practice of photography so universal as it deserves to be.

Mr. W. Crookes' photographic copies of the phenomena of polarised light in crystals of nitrate of potassa, and of calcareous spar, though interesting, do not appear to bear so directly on the progress of photography, though the difference of effect on iodide of silver producing the normal figure, and on bromide of silver producing an abnormal figure, may suggest a hint to our scientifically inquisitive readers.

The applications of photography to portraiture and to landscape and architecture, as might be expected, are very numerous. Mr. Roger Fenton takes the lead in point of quantity and variety of subject, and many of the specimens are of very high quality. But the large photographs of the cloisters of St. Trophimus, at Arles, and other architectural views by M. Baldus, must be admitted to surpass him; and in the instance of Burnham Beeches, Sir W. Newton has been more successful. Mr. Hennah's portraits are the best in the exhibition, excepting a frame of exquisite productions—portraits and groups—from collodion negatives, by the Ladies Neville. The Hon. H. Kerr also takes a distinguished position with a view of the High Street, Guildford, and three other views in Surrey, from talbotype negatives, which are first-rate. Viscount Vigier exhibits a number of large views in the Pyrenees, many of them of high character; but our space will not allow of special comment in this number of our Journal, either on these or numberless beautiful examples by Mr. Rosling, Mr. Owen, Mr. Sedgfield, Dr. Diamond, and other distinguished photographers who have contributed to make this exhibition so attractive and interesting. We should warn our readers that it will close at the end of the month, as the galleries will be required for other purposes.

A new weekly paper has just been started in Paris, principally devoted to photography, under the title of *Le Propagateur*, which apparently proposes to become the censor of the Parisian photographers, as the prominent feature in it is a crusade against what it considers the abuses among them.

M. Duboscq has introduced a modification of the refracting stereoscope, which he calls the Cosmorama Stereoscope. It greatly enlarges the views, and is said to be very advantageous to the general effect.

A PETITION in support of this bill for the adoption of the metric weights and measures, which will be introduced in the House of Lords by Lord Belhaven and seconded by Lord Kelvin, is being extensively signed throughout the kingdom.

ON SIMULTANEOUS DEVELOPMENT AND FIXING.

THE question of dichroic fog recently raised by Messieurs Lumière and Seyewetz has an indirect connection with the subject on which these notes are to be written. They stated in the communications made to the Société Française de Photographie and elsewhere that dichroic fog could be caused by minute quantities of thiosulphate in the developing solution. It is well known that traces of a thiosulphate cause extraordinary results when judiciously introduced into the reducing solution, and that MM. Lumière's statement has some truth in it seems obvious from many common results that occur in everyday work; but it is a noticeable feature of combined developing and fixing that no dichroic fog whatever is evinced. Nor does the introduction of hypo into the developer cause any great increase in the speed of action of the latter. The two main features to be aimed at in the experimental work were (i) to equalise the times required for complete development and fixation, or, at any rate, to arrange that development is complete before fixing, and (ii) to obtain a developer which would act energetically in the presence of so potent an agent as sodium thiosulphate.

The rate of fixing, as is well known, depends upon the thickness of the film and the amount of silver iodide which it contains; both these are matters of importance at first sight, because it would seem that not a great quantity of hypo could be combined with the developer. Experiment has shown, however, that as much as 25 per cent. can be employed, provided a suitable developer be used in conjunction with it.

It is hardly necessary to say that the developer must be one particularly free from fog in its working; it must also be one which will act well with sodium or other hydroxides, and the number available is, therefore, considerably limited.

As the use of a caustic alkali is almost essential, it is clear that pyrogallol, amidol, and other developing agents which are similarly sensitive to caustics cannot be employed, more especially as the quantity necessary is large.

The agents which gave the most promising results were (i) edinol, (ii) hydroquinone, both of which gave negatives almost free from general fog.

A typical formula is composed as follows:—One part of the developing agent, ten parts of sodium sulphite or one and a-half of potassium metabisulphite, two to three of caustic soda, ten of sodium carbonate, and 100 parts of water. It is possible to use a caustic alkali entirely and dispense with the carbonate; but this is not advisable even in the case of hydroquinone. To such a solution as this is added from ten to twenty-five per cent. of the total bulk of sodium thiosulphate.

The method of working most useful in practice is to keep stock solutions containing everything except the reducing agent, which is added just before use, as no developer containing caustic potash or soda will keep for any length of time. The two following formulæ are the best out of a considerable number made up in the course of experimenting:—

A.	
Water	200 cc.
Hypo	20 grams.
Caustic potash	10 "
Potassium metabisulphite	3 "

B.	
Water	200 cc.
Hypo	20 grams.
Sodium sulphite	10 "
Sodium carbonate	20 "
Caustic soda	4 "
Potassium metabisulphite	3 "

A form of A., to which attention must be drawn, and which may be termed C., is the same as A., save that for the ten grams of caustic potash two are substituted, together with ten

of sodium carbonate. The proportion of carbonate to caustic is thus 5:1, and this ratio seems in every instance to give the best results.

Just before use add to A. two grams of hydroquinone, to B. two grams of edinol, and to C. two grams of edinol. We then have three combined developing and fixing solutions sufficient to show the experimenter to what extent they will answer the double purpose. Before proceeding to describe the actual operation, however, it will be interesting to look at the subject from a theoretical point of view, as the entire process is apparently unorthodox and difficult of explanation.

The following seems the only theory which stands examining from all points of view, and is probably correct in part, if not in its entirety. If we consider the two outermost layers of an exposed film, say, n thousandths of an inch thick, n probably being small, and that the film is immersed in the combined solution, then these two layers will at a certain time be moist with the absorbed liquid. Hypo being the most active agent, it will dissolve out the silver bromide, and probably the light-affected silver bromide or "photo-bromide" as well; but to accomplish this the minute quantity of thiosulphate present in the amount of liquid absorbed will be exhausted, and hence the reducing agent left will be free to perform its work upon the layer immediately underneath the top one. If this be not true for successive layers, it may, at any rate, be so for neighbouring granules of silver gelatino-bromide.

In any case, development proceeds, as a rule, very rapidly; that is, the image appears much more quickly than when using an ordinary solution. During the discussion that followed the reading of my paper on this subject at the Royal Photographic Society, surprise was expressed by more than one that it should be possible to develop with so much hypo in the solution as even 10 per cent. But up to 25 per cent. can safely be employed, and by placing the formula of an ordinary all-round developer and that of a "combined solution" side by side, the slight difference necessary to render this possible is seen to be almost trifling.

Ordinary Developer.	Combined Developer and Fixer
Edinol	2 Edinol
Pot. metabisulphite	3 Pot. metabisulphite
Sod. sulphite	10 Sod. sulphite
Sod. carbonate	20 Sod. carbonate
Water	200 Water
	{ Sodium hydroxide
	{ Sod. thiosulphate

The formulæ A. and C. appeared to give the best results with dry plates, whilst for lantern-plates B. was more satisfactory, the smaller amount of hypo being advisable where thin film exists.

The two most noticeable things in connection with the working of these combined solutions are as follows:—First, the edinol-caustic formula is so vigorous that only a fraction of the normal exposure is necessary for a plate to give a good result; and, secondly, the image appears quicker than with an ordinary developer.

In some cases lantern-slides which had received only one-quarter of the exposure requisite under ordinary conditions came out just as though fully exposed, and the detail evident in the shadows, and throughout the whole picture, indicated that the exposure had been sufficient. Another thing worthy of notice in this connection is that if four or five lantern-slides be exposed varying lengths of time, say, for fifteen, eighteen, twenty, and thirty seconds respectively, and these be all treated in the same bath, the results will be very similar, this showing that control in development is not an easy matter.

There is a universal fog over the whole picture, which is slight in some cases, but always apparent. Experiments were made in which bromide was added in different strengths,

was readily observed that it assisted in producing a more contrasty image.

For the dry-plate work exposures were made by means of a Chapman-Jones plate-tester, and this gave a good idea both of excessive density which could be obtained and of the amount of fog produced. Plates exposed in the Hürter and Driffield sensitometer were then examined, and it was found that gradation of the plate was produced in a very even form. The plate was cut into two parts, both of which (strips) were exposed at the same time. One was developed with "Standard" citric oxalate, the other with a combined solution like C. The curve of the first portion was steep, the merging from excessive density to clear glass being abrupt, whilst the latter portion showed a regular stepping of the densities, and gave an almost ideal curve. This was also borne out as nearly as is possible by the Chapman-Jones tests.

Optimising the above work, it may be stated that it is quite possible to have 20 per cent. of hypo present in a developer, though caustic soda or potash is almost essential in that case; simultaneous development and fixing is not only possible, but practicable; that the number of agents which can be employed for the purpose is limited, those which work very free from fog alone being of use.

A few experiments in the direction above indicated will be very interesting, and, if necessary, convincing as well.

T. THORNE BAKER, F.C.S.

THE Kodak Catalogue.—In sending us a copy of their new price of general photographic goods for 1904, Messrs. Kodak, Ltd., state:—"This first issue of our list contains upwards of 800 pages of 1,000 illustrations. As well as including our Kodak goods, it sets forth every well-known line of photographic apparatus, films, and accessories. We have prepared this list in response to many requests from our dealers, and have specially stocked a large section of our premises at 41-43, Clerkenwell Road for the purpose. As a further convenience, we have arranged to keep a stock of these general goods at our Liverpool and Glasgow houses, also at our City, West-end, and other branches, so that dealers may use these depots to secure the most prompt supply possible. Anything which is either necessary or useful to the photographer will be found in this list."

The use of the Cinematograph for Scientific Purposes.—By means of the cinematograph it is possible to show to the eye the whole course of a visible phenomenon, either at the rate at which it actually happens or at any faster or slower rate that may be desired. Already it has been made use of to exhibit many phenomena the actual rate of happening of which is too rapid to admit of direct visual perception, as in the case of sound-waves and the flight of bullets; but it would seem to be as great possibilities of useful application to the progress of slow motions perceptible. For example, in R. F. M., in "Nature," the changes in a cloudy sky are so gradual that it is difficult even for a close observer to form a definite mental picture of what has happened in the upper air, say, a few minutes or a few hours. This difficulty is due, not only to the slowness of the changes, but to their complexity. But if we take under favourable conditions a good cloudscape could be photographed, say, 500 times in an hour, and the results put through the cinematograph in one minute, it could hardly fail to help the astronomer to get a clearer idea of what really happens above, especially as for purposes of study the same phenomena could be made to pass before the eyes of the student as often as he might wish. Perhaps our meteorological observatories may carry this idea far. Again, suppose a similar application made to the growth or flowering of a plant. I imagine that few botanists have the patience and power of concentration that would be required to clearly define an idea of such a process by direct observation. One could easily acquire by the aid of the cinematograph; even supposing a botanist possessed a perfect mental grasp of the process, if he wished to describe it to an audience would he not find the kinematographic representation of it an invaluable aid? Doubt many other possibilities will suggest themselves at once to the reader.

ELIMINATION OF HYPO BY MEANS OF BARIUM CHLORIDE.

THE suggestion made by Mr. John Noton in your issue for January 1st, page 18, that barium chloride is an efficient eliminator of "hypo" is not only valueless, but actually prejudicial to the life of the "photos," whether they be prints or negatives.

In the first place, the reaction that occurs when barium chloride and thiosulphate of soda are mixed together is as follows:—

Now, sodium thiosulphate is an extremely soluble salt, approximately, at 15 deg. C., one part is soluble in 1.5 parts of water; but barium thiosulphate is a comparatively insoluble salt, one part being soluble in about 250 parts of water, and therefore it is extremely possible that it would be thrown out on the "photos." But as one cannot ignore the fact that not only is the sodium thiosulphate on the surface of the print or negative, but also in the image-bearing film itself, it is obvious that the barium thiosulphate would be formed in the image-bearing film, and therefore we should have to remove a much less soluble salt than the sodium thiosulphate, and if a salt is less soluble it must obviously require more water, or, in other words, longer washing to remove. I think the above considerations prove that there is no advantage in forming barium thiosulphate.

Now, to prove my second statement, that the use of barium chloride is actually prejudicial to the life of the prints. Mr. Noton seems to have entirely ignored the existence of any other salt than "hypo"; but this one cannot do. Hypo is used to dissolve insoluble salts of silver, which are sensitive to light, and which, if left in the "photo," would gradually darken on exposure to light. Now, all printing-out silver papers depend primarily on the light sensitiveness of silver chloride.

When a print or negative is fixed, thiosulphates of silver are formed. I do not propose to enter into this question, but merely state the fact, and, taking but one of them, $\text{Ag Na S}_2\text{O}_3$, if barium chloride were added in sufficient quantities, we should have silver chloride, sodium chloride, and barium thiosulphate formed, according to the equation:—

The silver chloride might or might not dissolve in the barium hyposulphite; from a superficial test I have made I should say it would not. Anyway, a pure chloride lantern-plate was fixed with hypo solution made with distilled water, rinsed in distilled water, and then immersed in 5 per cent. barium chloride solution made with distilled water, and thoroughly well washed with distilled water. A comparison plate was treated in the ordinary way—that is, with an ordinary fixing bath, and washed by repeated changes of tap water. The plate treated with barium chloride is decidedly milky, and on exposure to light for 4 hours shows a brownish tinge, whilst the other plate is perfectly clean and clear.

Mr. Noton's heavy insoluble precipitate, which can be swabbed off, may be the comparatively insoluble barium thiosulphate, or insoluble carbonate or sulphate of barium, due to the hardness of the water that is used.

The conclusion I arrive at is, therefore, that the process is not one that commends itself to the practical man who wants to save time in washing or to produce permanent prints.

E. J. WALL.

THE Camera Construction Company have removed to a new factory, Eagle Works, Durham Grove, Morning Lane, Hackney, N.E. (seven minutes from Hackney Station, North London Railway).

THE Ansco Competitions.—Messrs. Charles Tyler and England Brothers, Limited, of 79, Copenhagen Street, Caledonian Road, King's Cross, London, N., inform us that the competition in connection with their Ansco paper closes on the 29th inst.

THE DECIMAL AND METRIC SYSTEMS.

[A paper read before the London and Provincial Photographic Association.]

INTRODUCTION.

IN order to appreciate the metric system of weights and measures it is necessary to be thoroughly at home in the decimal system of notation, for it renders the reading and calculations of metric weights and measures so simple that the one may be looked upon as the natural sequence of the other. That the decimal system should have been so long in being generally taught and adopted is really remarkable, seeing that our system of notation is based upon the figure "10," and is in fact a decimal system not carried through to fractional decimals, but so ingrained in our manner of writing and handling figures that we are apt to overlook the fact, and we should no more think of adopting another system than we should of changing our alphabet. It is, indeed, but a small step further to adopt the decimal notation throughout, and it seems singular that a decimal system of sub-dividing measurements of length, area, space and weights should not have been adopted much sooner and brought into harmony with the system which we have used from time immemorial.

The superiority of the one over the other is evident when we write

1849

instead of writing as the Romans did

MDCCCXXXVIII.

Multiplication or calculating the square or cube root of such a figure with the Roman system must have been a delightful operation. Now we all know that if the 9 in our example means 9 units only the 4 means 4 tens and the 8 means 8 hundreds without any further specification. When we extend that same system, which is as old as the hills, and is said to have been invented by the Arabs, denoting quantities of less than one unit of anything we follow exactly the same plan, and we obtain instead of tens, hundreds and thousands, tenths, hundredths, and thousandths of the unit or last figure after which they stand. In other words fractions of which the denominator is always a ten, a hundred or a thousand. It will not be necessary to work this out by any special examples. I expect an intelligent audience like the present one to be acquainted with the facts, and more or less with the decimal system; but I lay stress on this because it will lead us up to a thorough understanding of the metric system of weights and measures, which is based on these facts, and there is now hardly any exact calculation of any scientific subject undertaken, except by the aid of the decimal system. It has been urged by some opponents that the figure "10" does not divide as well as the figure "12," which is divisible by four figures, while ten is only divisible by two. These people are not free yet from the incubus of the vulgar fraction, and have not grasped the nature and value of the decimal system. A duo-decimal system would be better if our system of notation were duo-decimal, but nobody thinks of proposing such a change, and the two systems in conflict would be worse than putting up with vulgar fractions and undecimal divisions of measurement. They are in fact missing the point entirely, for it is not a question of computing a perfect system of counting, but of bringing existing systems into harmony. In a duo-decimal system we should have four single figured duo-decimals, viz. :—

- $\frac{1}{2}$ would be expressed by 0.2
- $\frac{1}{3}$ would be expressed by 0.3
- $\frac{1}{4}$ would be expressed by 0.4
- $\frac{1}{5}$ would be expressed by 0.6

while with the decimal system we have only two single figure decimals, viz. :—

- 1.5 which is expressed 0.2
- $\frac{1}{2}$ which is expressed 0.5

but we have no difficulty whatever to express any other fraction in decimals, though they may require two or sometimes three figures.

The argument is a superficial one, and can only be supported by those who have not grasped the principle of a decimal system. Other opponents urge the long array of figures against the decimal system, but I can prove that for all purposes it requires less figures to write a quantity in decimal figures than in vulgar fractions, and that calculations, such as multiplication and division are infinitely shorter and simpler. Let us take a simple case of calculating the area of a half plate—say for the purpose of a block—we have $6\frac{1}{2} \times 4\frac{1}{2}$ —in

decimals we have 6.5×4.75 . Not only is the latter written more quickly, but the multiplication is much simpler; we have one operation, plain multiplication, while with vulgar fractions we have reduction to one denominator first, and then division for multiplication by fraction is really division.

It will be seen presently how the handling of metrical measurements is intimately connected with the decimal notation which is the backbone of the metric system, facilitating calculation in every way and giving us always one kind of figures only, which always stand the same definite relation to one another; the relationship of "10" on its multiples—giving us the easy estimating of percentages, solutions, and of the absolute estimation of the strength of the essential ingredient. The early teaching of decimal fractions and closer acquaintance with them should be the precursor of the teaching and adoption of the metric system generally, according to the old adage: Acquaintance softens prejudice. Attempts to introduce the metric system in England have been repeatedly made. Legal speaking it is now a permissible system. We are not obliged, but we may use it. I for one have made extended use of this permission of Parliament, though I cannot say whether I used it before or after the permissive Act was passed; and I only hope the Act has retrospective consequences on those who did use it before it was passed, as I might become a martyr to science!

There is a Decimal Association in London, composed of Englishmen, many of them not knowing a word of French, but advocating the adoption of the metric system of weights and measures as compulsory system in Britain. I have to thank their secretary for the help they have given me to bring this matter before you. They have laboured for years, and are still doing all they can to get the system adopted in England, as it has been in every civilised country in Europe, and by many beyond. In the United States of America the system is also a permissive one, but is more largely used than in Great Britain. I have here a small instrument, made in America, illustrating one of those Yankee notions showing how they quickly grasp the neatness of the system. It is a steel ruler one decimetre long, one centimetre wide, one millimetre thick, and subdivided in cm. and mm. Its body or volume is exactly one cubic cm. Its weight is the specific gravity in grammes. The present Secretary of State for War, the Right Hon. H. O. Arnold-Forster, is one of the Parliamentary advocates of the metric system, and has obtained the support of over 200 members of Parliament for making the metric system legal and compulsory in Britain. He quotes in his book "The Coming of the Kilogram," the acknowledgment of Mr. A. Balfour, our Prime Minister, of the superiority of the metric system as follows:—"There can be no doubt that the judgment of the whole civilised world, not excluding the countries which still adhere to the antiquated system under which we suffer, has long decided that the metric system is the only rational system."—House of Commons, 1895. There are reports of many British Consuls abroad pointing to the fact that we are losing trade in many quarters through the retention of the old system of weights and measures which are not understood by these would-be buyers, and which always they will not take the trouble to study in the face of their own intelligible, simple, and rational system. For us photographers the system is in every way deserving of attention.

A few weak efforts have already been made. Some time ago the Photographic Club made the heroic resolution that all measurements and formulæ should be stated in the metric quantities, drams and ounces being banished out of sight—in fact, decreed the adoption of the metric system. I was not of the committee charged with investigation and drawing up of this momentous proclamation. I was probably the only one who constantly used the metric system and no other, and who has used it ever since, while I have not since heard anyone in that enlightened body state any formulae in metric quantities, every one thinking that his was an exceptional case. So far, the success amongst us photographers. I recollect an instance which illustrates the want of understanding on the part even of the leading lights. It was urged—and justly so—that solutions should be made up in correct percentages, containing a given quantity of the dry salt, not in (say) 100 or 1,000 of fluid, and holding it in solution, but in so much that the total should make up a definite measure of solution—say, 100, 500, or 1,000. A well-known platemaker interjected that he did not see the difference, and that one was as good a 2 or a 5 per cent. solution as the other.

was a platemaker: what would you expect of an amateur? Another instance shows how little acquainted we still are with metric quantities. A lecturer at the Royal Photographic Society described the volume of water that could be stored by the new Nile dam at Assuan, lately built, as so many millions of cubic centimetre, instead of cubic metre—an error of only one million times less! The remark passed unnoticed, except, probably, by the speaker. The public visiting the lantern entertainments at the R.P.S. is naturally more artistic than scientific. Such instances show that we are not over-conversant with the metric system, and our acquaintance with it will stand strengthening considerably. My object is to strengthen that acquaintance amongst my fellow-photographers. It is only in a very limited degree. I propose, therefore, to use a few examples of illustration, and to sketch to you a few comparative figures under both systems.

THE METRE.

We have now to come to close quarters with the actual metric measurements of length, surface, capacity, and weight, and I must now claim your attention for a short time in order to analyse the system and study its advantages as compared with the one we are now using. The metre—from the Greek "metron," a measure—is the basis of the system, and was established in 1795, after the French Revolution. Its length was intended to be one 10-millionth part of the quadrant of the earth, from Pole to Equator. This point has been disputed, but it is not of any consequence. The normal metre is exactly 39.371 inches, or 39 $\frac{3}{4}$ nearly. We now come to a feature of the system. The divisions and multiples of the metre are named in one plan.

The divisions are designated by Latin prefixes and the multiples by Greek prefixes. Thus the metre is subdivided into 10, such as a tenth is called decimetre. The decimetre is divided into 10 centimetre. The centimetre into 10 millimetre.

The multiples proceed on the same plan. The decametre is 10 metres, the hectometre is 100 metres, and the kilometre is 1,000 metres each, one being 10 times the former. Thus we have on one plan a system by which we can measure from the minutest dimension used in optics or the science to the distances of a geographical description. I will at once show you that the decimal notation is the backbone of the whole system, and that without being conversant with it, the charm and simplicity of the metric system cannot be taken advantage of to the full extent. If with our present Imperial system we wish to express a measured distance from one point to another we do it in miles, furlongs, rods, yards, feet, and inches. Taking an example at random, we may say, 1 mile, 3 furlongs, 20 rods (or poles), 2 yards, 1 foot, and inches.

This distance measured by a surveyor may be stated in yards, but there are no means of assimilating the various measurements into one figure except by stating it in feet or inches. If we were to express a similar distance in metric measurement we should not write 2 kilometre, 5 hectometre, 4 decametre, 8 metre, 6 decimetre, and 3 centimetre; though perfectly correct this would appear ridiculous. The whole figures would be linked together and treated as kilometer and fractions (decimals) of it, or as metres and decimals, and it would stand thus:—

2.548.63 m.

The decimal point put between the 2 and the 5 would denote kilometre, and between the 8 and the 6 would be stating it in metres, while we should at once know that we have a distance of 2 $\frac{1}{2}$ kilometer, roughly speaking, or 2,548 meter and 63 decimals. The relationship of these figures, though they denote definite lengths, is the same as those in the number 1848, and the handling of them is equally easy as compared against the Roman MDCCCXXXVIII.

I think I have shown you that the decimal system must be thoroughly understood in order to fully appreciate the metric system. The advantage of being able to treat the minor length simply as a decimal of the larger is again not only in brevity, but also in simplicity, ease of calculation, and precision. The same principle applies to surface measurement, the basis of which is the square metre. The subdivisions are in tenths of the base, and the resulting superficial areas as the square of ten. The square metre is equal to 10.764 feet, or approximately 10 $\frac{3}{4}$ square feet. The square decimetre based upon the one-tenth is therefore the 100th part of the square metre. The square centimetre by the same logic the 100th part of the decimetre, or the 10,000 part of the square metre. The multiples of the square metre

increase in the same manner as the square of 10. One decametre is 100 square metres, one hectometre 10,000 square metres, and one kilometre 1,000,000 square metres. The reduction of any of these into its components or multiples is as easy as that of the linear measurement. The usual way to express a surface of land is by the "are," which is equal to 10m. square containing 100 square metres. It is, compared with our acre, about $\frac{1}{4}$ of it, and equal to 119.603 square yards. The multiple of the are, used for large surfaces of land, is the hectare (hecto-are), 100 ares or 10,000 square metres. The hectare is equal to 2.47 acres, roughly 2 $\frac{1}{2}$ acres.

We now proceed to consider the cubic measurement. It is built upon the unit of the metre, and progresses on the same plan by the multiples of "10." The volumes or capacities resulting are progressing by the cube of 10, or 10 \times 10 \times 10. A cubic metre is a large measure used for measuring big volumes, such as water, fodder, earth, and so on. Its capacity is equal to 35.32 cubic feet, or 27 $\frac{1}{2}$ bushels. It divides into 1,000 cubic decimetre. The cubic decimetre is the 1,000th part of the metre, and divides in its turn into 1,000 cubic centimetres, a small volume with which most of you will be somewhat familiar through reading chemical formulæ from French, or, perhaps, German papers. Its sign is ccm. or cc. We shall presently make the closer acquaintance of these two subdivisions, for one is the basis of our weights, the gramme, and represents as a unit the weight of so much water at its greatest density, 4deg. C. or 39deg. F., and under normal barometrical pressure. The other is, consequently, a thousand times larger, and has the weight of one thousand grammes, or a kilogram. It is the well-known kilo of commerce. This at once establishes the connection between the weights which we use with the measure of length as well as of area and capacity. In fact they are all instances of the same system based upon one uniform, simple, and intelligible plan, the simplicity of which becomes more potent as we advance, and which stands out strongly against our disjointed system of unsympathetic and muddled-up crowd of weights and measures.

I have here a model of cardboard. I may at once say that it is a home-made model of the cubic decimetre. Its capacity is the litre, its weight when filled with water would be the kilo—1,000 grammes. The other model is the gramme or cubic centimetre, being 1,000th part of the first in capacity and weight of any equal substance. We have now to consider first, measures of capacity, and second, measures of weight. The basis for the cubic measurement for liquids, corn, grains, and the like, is the litre. The litre, as I have already pointed out, is the same volume as the "cubic decimetre." The litre is equal to 1.76 pints, or 35.20 ounces. The cubic centimetre being only 1,000th part of the former, it is necessary to make another subdivision without, however, at all forsaking our principle, the decimal scale of gradation.

We have seen that the cube built upon the next metric sub-division, the cubic centimetre, is in capacity 1,000 times smaller than the cubic decimetre. We require, however, in order to measure liquid quantities a handy measure for two or for three-tenths or five-tenths of the litre. Hence the litre is divided into 10 decilitre, the decilitre into 10 centilitre, and the centilitre into 10 millilitre, and we have arrived at the capacity of a cubic centimetre, which is, as its name denotes, the 1,000th part of the litre, and the weight of its contents in water is one gramme. The unit of our system of weights. The multiples of the litre are the decalitre, or 10 litres, hectolitre, or 100 litres, and kilolitre, or 1,000 litres. Again I may remind you that the kilolitre, or 1,000 litre, has the capacity of one cubic metre, a measure used for large quantities of fluid, such as the contents of a lake, a reservoir, and the like, while for such liquids as wine or beer the hectolitre is used. In writing down a given quantity again the decimal system would be used, and instead of writing say, 36 hectolitre, 4 decalitre, and 7 $\frac{1}{2}$ litre, the one set of figures, 3647.5 would denote the same thing, the decimal stop between the 7 and 5 marking the number of litres and fractions of it. As a handy measure there is such a thing as a double decilitre and a half or 5 decilitre. The latter is still known as a pint, which, indeed, it is near to in size, standing as it does between the reputed pint of 16 and the Imperial pint of 20 ounces. When we come to compare this system with our system of pints, quarts, pottles, gallons, pecks, and so on, it shows more than any of the previous comparisons have done the superiority of the metric system.

MEASURES OF WEIGHT.

You know already that the unit of weight is the gramme. By an ingenious device the system of weights is brought into harmony with the system of measures for length, surface, and, above all,

capacity. The "gramme" is the weight of so much water as can be got into the space of a cubic centimetre taken at 4deg. C. or 39deg. F., at a barometrical pressure of 30in. It is then that water is at its greatest density. This plan brings the system of weight into complete harmony with the system of measures, and enables us to treat solutions on a rational basis, because the weight of the body in solution weighed in gram agrees with the dissolving fluid—1 gram of a salt dissolved in, say, 99 of water makes a 1 per cent. solution, and the quantity of solution will weigh exactly 100 grams. This is accomplished without any calculation, and, moreover, cannot be done with any unit of weight or measure that we use in our antiquated system.

The subdivisions of the gramme are—

0.1 gramme	Decigramme.
0.01 gramme	Centigramme.
0.001 gramme	Milligramme.

The multiples are—

The decagram	10 grammes.
The hectogram	100 grammes.
The kilogram	1,000 grammes.

The kilogram is the weight of a litre of water at 4deg. C., the capacity of which, again, is that of the cube model before you, which, when filled with water, will weigh one kilo. There remains only to add that the "metric tonne," which is 1,000 kilogrammes (and equal to ten times our double hundredweight) is used for large quantities of heavy matter, such as earth, coal, etc. It is almost needless to say that the same treatment is applied in writing out figures of combined weights by simply placing them together and treating the fractions of the unit as decimals, as shown you with regard to surface and cubic measurements. The tables herewith presented show the whole system at a glance. The equivalents, having a common basis, are placed on one line, so that anyone not conversant with the names can always trace their exact comparative value. We have now described the principle upon which the metric system is based, and it only remains to compare points in the metric system with our own. This cannot be done at all in a thorough-going manner, as the time for such a task is beyond that allotted to such an address as mine; but a few instances will serve to illustrate it and to show you the disadvantages under which we labour with our present antiquated system.

[Tables shown.]

We have now sufficiently satisfied ourselves that the metric system is better, simpler, and more rational than our broken-up and disjointed conglomeration of systems, and I have shown that hand-in-hand with a metric system must go the teaching of the decimal system which is its backbone. The teaching, as far as we are concerned, should be taken up by our polytechnics and all teaching institutions, whether for young or adult, and no photographic school or instructive system of any kind should be without it. There would be an excellent opportunity for the Royal Photographic Society to help in spreading the knowledge amongst photographers by not only recommending the metric system, but by publishing tables and general information on it amongst its affiliated societies. It is only by such action that the change, which is openly acknowledged to be desirable and badly needed, can be brought about. I have now to touch upon a subject which is usually treated as a sort of an appendix to the decimal system. It is the measuring, not of length or areas or weight, but of *value*. It is urged that when changing our measurements, the measure of values should be included. All civilised countries have adopted a decimal system of dividing their coinage. We alone adhere to a system with three values—pounds, shillings, and pence—and we divide them in a non-decimal manner.

No one desirous of seeing another system of dividing our monetary values thinks of advocating the abolition of our excellent standard or an adoption of a mixed standard like the French; but the point on which all are agreed is a decimal division, so that in many calculations the same advantages could be enjoyed as are present with a decimal system. S. Jackson, M.A., advocates in his metrical tables a system of coinage in which the pound (£) is divided into 10 florins, the florin (fl.) into 10 cents., the cent. (c.) into 10 mills. The standard would remain gold, all silver coins would remain except the 3d. piece. The bronze coins would disappear and be replaced by 5, 2 and 1 mills. This system, no doubt, would have its merits. It leaves us,

however, with three divisions. A simpler system would probably be one with two divisions. This would be accomplished by retaining the pound as a coin only, and not using it in accounts as a unit. It would not affect the money standard, which might remain gold, and the silver coins would still be token coins as they are now, and the copper coins could be retained as they are in such a system the divisions might be dollar or crown and cent. The crown equal our present 4s. piece would be equal to 100 cent, our present half penny would be the cent, the penny a double cent. The 1s. and 2s. pieces would still be as useful as they are now. The sovereign would be five crowns or dollar, and a double sovereign would be ten dollars. Accounts would be kept in crowns and cents., or dollar and cents., as they are in Canada, where for the matter of that the (£) sovereign is held in as high estimation as at home, while all money calculations would be enormously simplified; such a figure as £45 12s. 8d. would read \$183.16, the 16 being decimals of the 3, the unit of the dollar or crown column, and the only change would be that instead of the crown having as now 96 halfpennies it would be equal to 100 cents; in other words the halfpennies would be serving a cent, and 100 would be equal to one dollar or whatever the coin might be called. What the silver coins would gain the bronze coins would lose. Both are only token coins.

I have now only to conclude. In the present day of fiscal agitation there is one point I wish to press home. If we are to regain the trade we have lost through hostile tariffs of Continental and other nations we shall not regain it unless we can present British made goods in money values and in measurements that are entirely incomprehensible to those whom we wish to be their purchasers. We shall never do it with pds and pounds, nor with furlongs and feet, or gallons and gills. And if we have lost much of the trade formerly held by our manufacturers, who can tell how much has been lost by the very fact that we have not up to now seen our way to change the antiquated system under which we ourselves still continue to suffer?

J. R. Gorz.

SOME PECULIARITIES OF COMETS' TAILS AND THEIR PROBABLE EXPLANATION.

[A paper read before the Chicago Meeting of the National Academy, November 18, 1903.]

BEFORE the application of photography to the investigation of cometary phenomena the study of these bodies was beset with many difficulties. In fact, most of the changing phenomena of the tails of comets were then wholly unknown, and, hence, their study impossible. The study of the physical condition of comets' tails may be said to have had its beginning in the past ten or twelve years. In that interval, though no great comet has appeared, the photographic plate has faithfully portrayed some of the most extraordinary phenomena, such as have to a great extent revolutionised our ideas of these erratic bodies. This, too, has occurred in the case of comets which with the older method of observing would have promised little or nothing of interest. The remarkable phenomena presented by Swift's comet of 1892 were the beginning of these revelations. These were followed by similar appearances in Rordame's comet of 1893 as photographed by Professor Husey. But a new series of phenomena appeared in Brooks' comet of 1893, which were suggestive of a wholly different explanation to those of Swift's and Rordame's comets. They suggested an outside influence foreign to the comet itself and of an extremely important nature. The last comet sufficiently active to produce anomalous features was Borrelly's, of the present year. This object, though it failed to fulfil the promises of a spectacular naked eye affair, showed a remarkable change in its tail on July 24th, which will perhaps throw more light on cometary phenomena than any other comet has yet done. Though, unlike, Brooks' comet of 1893, it suggested no outside influence, it yet presented an appearance that seems to offer itself to a satisfactory explanation, and which leads to a definite knowledge of the motion of the particles composing the tail, and of the interval of luminosity of these particles when free from the comet.

In the case of Swift's comet a large mass of matter—several times larger than the head of the comet—was shown in the tail drifting back from the head. This seemed to be due to the separation of an unusually large portion of the cometary matter by the disruptive

repellent force of the sun. Perhaps the most remarkable part of this phenomenon was that the mass looked like a secondary comet with several tails of its own. From an inspection of the photographs it is clear that this object had its origin in the head of the comet, being simply a cloud instead of a stream of the repelled particles. Its system of tails was doubtless produced just as in the case of the parent comet, by the repellent action of the sun. The numerous tails frequently shown in the photographs of this comet (and in others since) were, it would seem, produced by different centres of emission in the nucleus of the comet—jets or streams of matter, shot out from the different parts of the nucleus from different centres of activity. According to the general theory of a comet's tail, the action of the sun upon the nucleus of the comet produces a repellent action in the nucleus on the sun-ward side, and the particles are expelled by the comet are met by the pressure of the sun's light and driven back behind the comet to form the tail. This theory is sufficiently comprehensive to account for essentially all the visual phenomena of a comet's tail. But it does not satisfactorily account for the great number of thin diverging rays and thread-like streams shown by photography so often to be the main feature of the tail. Indeed, there are cases where a straight secondary tail or streamer makes a very large angle, 45 degrees—or more—with the main tail. It does not appear that the repulsive force of the sun alone can account for this feature. And there are other peculiarities in the tails of comets shown by photography which rather suggest that a comet has been to do with the production of its own tail than has generally been supposed to it, further than simply supplying the material for the making of the tail.

Brooks' comet of 1893 presented phenomena unique in character and not susceptible of the explanation offered for the previous comet. Indeed, the singular freaks of that comet's tail compel us to seek an explanation in some outside cause—inherent neither in the comet nor in the sun. The tail which one day was in a normal condition, was on the next broken and disturbed as if it had encountered some resisting medium in its flight through space. The disturbance seemed to come from the direction towards which the comet was moving. The succeeding morning it was badly broken and hung in cloud-like masses, some of which were entirely torn off from the tail and appeared to be drifting away in space. On another occasion the tail was concave towards the direction of motion, and had the appearance of beating against a current of resistance. It was disjointed in places, and near the end was abruptly bent at nearly a right angle, as if at that point it had encountered a stronger current of resistance. One examines these pictures there seems no escape from the conclusion that this comet's tail did actually encounter some resisting medium about the 21st of October, 1893, and for several days subsequent to that date; whether this was a swarm of meteors—such as we know exist in space near the sun, or some sort of resisting matter of which we as yet know nothing is a subject of time to settle. Photographs of Borrelly's comet on the night of July 24th showed a large section of the tail apparently completely broken off and displaced from the direction of the remaining portion of the tail; there was nothing in the appearance of this to suggest any outside disturbance. The section was straight and apparently uninjured. Other photographs made four hours earlier and three hours later showed that this section was receding from the comet and that the normal tail was growing in length. Determining the motion of the fragment from these photographs, it was shown that it must have separated from the head at 2.30 p.m., G. M. T. of July 24th. Photographs of the comet on July 23rd showed nothing of this phenomenon.

The explanation of this feature appears to be a very simple one. It would seem that, for some cause, between two and three p.m. of July 24th, there occurred a slight but sudden change in the direction of emission of matter from the comet. The first tail would then separate from the comet—as its supply of material would be cut off—and a new tail would begin in the new direction and grow to the normal length, while the section would drift out and dissipate to space. Thus would the phenomenon of July 24th be produced. The actual velocity of separation, determined from the photographs, was 29 miles a second. As the comet was approaching the sun at the rate of 22 miles a second, the real motion of the particles away from the sun was 7 miles a second. This is a rather small velocity

compared with some of those attributed to the particles composing a comet's tail.

This comet showed us that the tail actually moved out from the head as a luminous stream which remained visible for hours after its supply from the head had ceased. At the same time this section had a progressive motion laterally, which would partake of the original motion of the comet when the separation occurred. Let, therefore, this drifting stream encounter, say, a dense swarm of meteors, or some other resistance, and a disruption of its symmetry would occur—just as seems to have happened in the case of Brooks' comet of 1893. This feature of Borrelly's comet seems to have been unusually well photographed both in this country and in Europe. By a combination of measures of three photographs—the first at Nanterre, France, by F. Quénisset, the second and third at the Yerkes Observatory by the writer and Mr. R. J. Wallace, respectively, the following values of the hourly motion of separation of the tail from the head was obtained:—

Nanterre and first Yerkes Observatory plate, 10'.1. Interval 4h. 35m.

First and second Yerkes Observatory plates, 10'.7. Interval 2h. 59m.

The mean of these is 10'.4 for the hourly motion of separation. I am convinced now that the slight difference between the above two values is due to the uncertainty of the measures. The small scales of the photographs and the ill-defined condition of the comet would not permit any closer agreement if the motion were uniform.

It appears, therefore, that there is no evidence of acceleration in the motion of separation. This is contrary to what would happen if the particles had been driven away from the comet by the repellent action of the sun alone. For previous to its free existence the particle would be moving towards the sun with a velocity of 22 miles a second—as a part of the comet. After it had become independent and subject to the repulsive action of the sun, it would still approach until the repulsive force checked its speed, when for a moment it would become stationary and then begin to recede, at first slowly, and then with rapidly accelerating velocity. This would be its action if due alone to the repulsive force of the sun—or the pressure of the sun's light. Assuming the correctness of the generally accepted theory of cometary tails, the want of acceleration in the motion of the fragment is puzzling, and would rather show that the sun had little to do with its flight into space. Some exception may be taken to the explanation I have offered for the cause of the phenomenon of July 24th in reference to the sudden change of the direction of emission of the particles from the head. It is only necessary, however, to examine the series of photographs of Swift's comet—or, indeed, of almost any other comet—to see that changes vaster than this rapidly take place in the form of the tail. One day it will be made up of a dozen thread-like strands, and the next of but one broad stream. Small divergent tails will form and rapidly die away, and others spring forth in some other direction to take their place. I can see no objection to the supply of the main tail itself being suddenly stopped to break out afresh at some adjacent point, producing a phenomenon like that of July 24th. The facts still remain, however, and there seems to be no other satisfactory explanation of them.

PROF. E. E. BARNARD.

Yerkes Observatory.

PHOTOGRAPHERS IN THE UNITED KINGDOM.

FROM time to time we have published the numbers of persons following the profession of photographers in the various counties of England and Wales, as ascertained at the last Census, and we are now enabled to give the totals for England and Wales together with Scotland and Ireland, which are as follows:—

	Males.	Females.	Total.
England and Wales	11,148	3,853	15,001*
Scotland	1,187	1,082	2,269†
Ireland	449	228	677‡
Totals	12,784	5,163	17,947

* Including 264 persons of foreign birth. † Including 18 persons of foreign birth. ‡ Including 16 persons of foreign birth. Total, 298.

DR. D. H. SCOTT, F.R.S., has been elected President of the Royal Microscopical Society for the ensuing year.

THE FOURTH CHICAGO PHOTOGRAPHIC SALON.

[From the Official Catalogue.]

CONSIDERING the inconstancy of the "Salon movement" in other cities it may be inferred that four consecutive annual exhibitions establish a permanent custom in Chicago. At least it certifies that the Chicago Society of Amateur Photographers and The Art Institute regard the Salon as much more serious and important than a passing fad or divertissement. In plain fact it shows that the Society has faith in the "pictorial photographic" propaganda—faith of a much more lasting and sterling quality than anyone can appreciate who has no knowledge of the responsibilities, labour and outlay involved in the assembling of such an exhibition as that now on view in the galleries of the Institute. And the kind of faith which actuates the Society and The Art Institute must produce—is producing—praiseworthy fruits.

It will be recalled that the First Salon of this joint management, that of 1900, was a frank experiment, designed to discover what talent the Central West had in high camera craft. It was a Salon of the "Eastern cult," with only a few Chicagoans and Westerners adjudged worthy to enter the galleries. There was, true, much humiliation among our workers sincere men and women who had laboured in ardour and patience for many years to bring forth that which could command the hall-mark of "Art." The rejection of their cherished works and the hanging in their stead of utterly dissimilar pictures from the studios of the New Yorkers was a bitter disappointment to them; indeed, many thought it was a deliberate affront, a cruel snub at the hands of self-styled superiors whom chance had placed in the jury room. But thanks to the virility of the West this hasty opinion did not long endure. It was worthy only to die.

On reflection, our ambitious "camerists" were able to find, in the prints that came *hors concours* to the 1900 Salon, qualities which undoubtedly did justify their preferment over the home product. It was clear, after a little honest seeing and thinking, that the works of Mrs. Käsebier, Mr. Stieglitz, Mr. White, Mr. Dyer and Mrs. Schütze had great distinction of style and immense intellectual strength, as well as splendid artistry of technic and effect. The spirit of the West asserted itself. Incipient envy was snuffed out instantly. Generous praise of the great camera artists of the East was heard on every hand. What was best of all, serious, thoughtful, efforts were undertaken by all our home workers to emulate the excellencies of our New York fellows. Never was there more earnest, honest, fruitful self-educational work anywhere than in Chicago after the Salon of 1900.

Then came the Salons of 1901, 1902 each showing what the West could do—what had been done and learned since the Salon of 1900. By all testimony, it is competent to say, these exhibitions gave proof of growing power, and artistic grasp beyond anything which could have been anticipated. These Salons produced some truly master-workers—Willard, Lawrence, Detlefsen, James, Mrs. Gatch, Monteverde, D'Arcy Powers, Mins, Field, Clute, the lamented Bourke, the neo-Newark enthusiasts, and a score more in Chicago, San Francisco, Minneapolis, Cleveland, Akron, and elsewhere. All of them are working in the direct and unaffected manner of the prairie states to attain "those things which are more excellent" than mere "detail" or fatuous "finish." They, and all of us, are thinking with our lenses where we were wont to employ them mechanically. And there is springing up here in Chicago and the West a school of pictorial photography which is individual and distinct—no mere idle echo of New York and Philadelphia, but the strong, original note of a Western life and activity. There are no dawdlers and "button-pushers" among us now. Each in his own way, each after his own ideals, each limited by his own mental horizon—we are, one and all, striving to produce worthy works, photographs which are true children of the Muses. What is better, there is a general improvement that cannot be denied.

Now comes the Fourth Salon with a distinctively Western exhibition. Note in it the absence of superficiality and mannerism. Observe that it is frankly photographic, yet entirely subservient to the canons of art, obedient to the laws of arrangement in all branches, artistic in purpose, artistic in technic, artistic in ensemble—yet truly photographic. No sham at all anywhere; no pretence; no tinsel. We

have here a noteworthy advance toward the fulfilment of that Statute which is written:—

"In a fine art it is criminal to go beyond the means used in its exercise."

A sculpture needs no paint; a painting calls for no plastic comitants; an etching is rightly held sternly to the limiting condition of the needle point free from mezzo stipple; the mezzotint likewise scorns aid from the pure incised line and glories in the work of the wheel; and, finally, a photograph needs no concealment of its parentage—its father the lens, its mother the bromide plate, its quickening spirit the soul of the camera worker!

The Chicago Salon of 1903-4 marks a great advance in the long struggle toward the goal of the consummate art of the future; that art in which the soul of the artist is truly wedded with the genius of the chemists and opticians; that art in which the humanity to our day and generation is disclosed in all the beauty of the truth; in which human life, hopes, struggles, aspirations, failures and successes are written in that highest of all truth which is beauty!

LOUIS ALBERT LAMB.

THE R.P.S. ELECTIONS.

At the annual general meeting of the Royal Photographic Society on Tuesday last, the 9th inst., the result of the ballot for Officers, Council, and Exhibition Judges was announced as follows:—

President.

Sir William Abney, K.C.B.

Vice-Presidents.

The Right Hon. the Earl of Crawford, K.T., F.R.S.

Thomas R. Dallmeyer, F.R.A.S.

Major-General J. Waterhouse, I.S.C.

Sir Henry Trueman Wood, M.A.

Treasurer.

John Sterry.

Ordinary Members of Council.

Thomas Bedding.	Rev. F. C. Lambert, M.A.
Henry W. Bennett.	J. C. S. Mummery.
James Cadett.	Charles H. Oakden.
St. Lawrence Carson, B.A., B.Sc.	E. Sanger Shepherd.
Douglas English, B.A.	John Spiller, F.I.C., F.C.S.
Thomas E. Freshwater, F.R.M.S.	Joseph Wilson Swan, M.A., D.Sc., F.R.S.
Dr. C. F. Grindrod.	Professor William Cawthorne
A. Haddon.	Unwin, B.Sc., F.R.S.
Sir W. J. Herschel, Bart.	H. Snowden Ward.
John A. Hodges.	Benjamin Gay Wilkinson.
G. Lindsay Johnson, M.A., M.D., B.Sc., F.R.C.S.	

EXHIBITION JUDGES.

Pictorial Section.

Henry W. Bennett, F.R.P.S.	William Crooke.
P. H. Emerson, B.A., M.B. (Cantab), F.R.P.S.	J. C. S. Mummery, F.R.P.S.
	G. A. Storey, A.R.A.

Technical and Scientific Section.

Sir W. de W. Abney, K.C.B.	Chapman Jones, F.I.C., F.C.S.
Thomas Bolas, F.I.C., F.C.S.	F.R.P.S.
D. English, B.A.	E. Sanger Shepherd, F.R.P.S.
A. Haddon.	Major-Gen. J. Waterhouse, I.S.C., F.R.P.S.

Patent News.

The following applications for patents were made between January 25 and January 30, 1904:—

Int Trimmer.—No. 1,856. "Improved appliance for cutting photographic or other prints, or paper." James Davenport.
Sensitised Copying Papers.—No. 1,857. "Further improvements in the manufacture of sensitised copying papers." John Hawke.
Lenses.—No. 1,883. "Improved photographic lenses for cameras." Complete specification. Ferdinand Stark.
Cameras.—No. 1,902. "Improvements in photographic cameras." Complete specification. Maximilian Herz.
Dry-plates.—No. 1,925. "Photographic dry-plates." William Jerome Harrison.
Camera Attachment.—No. 1,977. "Process and apparatus for fitting a film-strip to a photographic camera intended for wider films." Complete specification. Maximilian Herz.
Envelopes.—No. 2,195. "Improvements in envelopes for developing photographic plates and the like." Alfred William Southey.
Printing Frame.—No. 2,219. "Improved photographic printing frame." John Batty.
Shutters.—No. 2,224. "Improvements in or applicable to photographic exposure shutters." Alfred Woods.
Apparatus.—No. 2,280. "Improved means for use in developing, fixing, washing, and drying photographic plates, or films." Alexis Olivier.
Shutters.—No. 2,363. "Apparatus for operating the shutters of photographic cameras." William Taylor.

FORTHCOMING EXHIBITIONS.

February 13-27.—Scottish National Photographic Salon. Exhibition Secretary, Alex. Mackenzie, 42, Scott Street, Perth.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Adwell, Essex.

March 5. Last day for entries February 18.—South London Photographic Society. Entry forms from W. Calder Marshall, F.C.A., Glenton Road, Lee, S.E.

March 5-12.—Brehin Photographic Association. Hon. Secretary, Kirk, 1, Infirmary Street, Brehin.

March 8-9.—G.E.R. Mechanics' Institution (photographic section). Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Mack, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 22 to April 5.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, U. King, Hurst Bank, Selsdon Road, Sanderstead.

An Edison Memorial.—Steps are being taken to celebrate the twenty-fifth anniversary of the introduction and commercial development of the incandescent lamp by founding a Thomas A. Edison Medal, which will be entrusted to the American Society of Electrical Engineers. The Institute, through its Council, has already accepted the trusteeship of this fund, and the circular which is being issued by the Edison Medal Association announces that it is the intention that the medal shall be awarded each year to the graduating student who shall present the best thesis on some original subject from the universities and colleges of the United States and Canada which give regular courses in electrical engineering. Mr. Edison's mother was a Canadian.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
11.....	Aberdeen Photographic Assoc.	Print Competition.
12.....	Watford Photographic Union	Portraiture. Mr. Harold Baker.
12.....	West London Photo. Society..	Members' Lantern Slides.
13.....	Ashton-under-Lyne Photo. Soc.	Chess Match, "B" League, Rochdale, home.
13.....	Burton-on-Trent Photo. Soc. ...	<i>The Eye Compared with the Camera.</i> Mr. A. W. Butterfield.
15.....	Glasgow & W. of Scotland P.A.	<i>A Month in Jamaica.</i> Mr. George E. Thomson.
15.....	Southampton Camera Club.....	Lecture Competition.
15.....	Bowes Pk. and District Ph. Soc.	Lecture Competition.
15.....	South London Photo. Society	<i>Some Notes on the Chemistry of Photography.</i> Mr. W. Marshall, B.Sc., F.C.S.
15.....	Hilford and District Photo. Soc.	<i>Trimming and Mounting.</i> Mr. J. Watson.
15.....	Royal Photographic Society	Lantern Meeting.
16.....	Rotherham Photo. Society	<i>Hand Camera Photography.</i> Mr. Wallis.
16.....	Glasgow Southern Photo. Assoc.	<i>Rotograph and Rotoz Bromide Papers.</i> Demonstrated. Mr. W. A. Sims.
16.....	Birmingham Photo. Society ...	<i>Two Holidays with the Camera.</i> Mr. W. A. Clarke.
17.....	Photographic Club	<i>English Gothic Architecture.</i> Messrs. J. Mann and T. A. Coyle.
17.....	Ashton-under-Lyne Photo. Soc.	Chess Match, "B" League, Oldham, away.
17.....	Bath Y.M.C.A. Camera Club..	<i>Developing by Tim's.</i> Illustrated. Mr. W. J. Hallett, M.P.S.
18.....	Hull Photographic Society.....	<i>Elementary Ootype.</i> Mr. W. J. Williams.

18.....	London & Prov. Photo. Asso. ...	Annual Supper.
18.....	Liverpool Amateur Photo. Asso.	<i>The Theory and Practice of Development.</i> Demonstrated. Mr. Fred. Anyon.
18.....	Southport Photo. Society	<i>Orthochromatic v. Ordinary Plates.</i> Illustrated. Mr. T. W. Charlesworth.
18.....	Gainsboro' Camera Club	Members' Night.

CAMERA CLUB.

AN extremely well thought out and practical paper was read on the 1st inst. by Mr. Nelson K. Cherrill, with the title, "A New Departure in Control Printing," and he had come all the way from Lausanne for the purpose of addressing the Camera Club of London. The paper really resolved itself into the description of the advantages to be gained by the employment of a new kind of printing frame which has been invented by Mr. Cherrill to meet the modern need for so dealing with a negative that the best "pictorial" effects can be gained from it. He starts with the assumption that no such thing as a perfect negative exists, and that better things can be obtained from the best by judicious treatment. The new frame makes it possible to do this in the most convenient way, while it abolishes the sundry rough-and-ready expedients which have hitherto been in vogue among photographers. It presupposes that the man who wishes to obtain the best results from a given negative is in the position of him who exclaimed, "Time was made for slaves," for there is no doubt that the processes recommended must consume much of that valuable commodity.

The essence of the matter rests upon such a perfect method of registration between negative and print which is in the frame that the print can be bodily removed any number of times for examination and immediately replaced in its proper position without any risk of shifting. And this is brought about by the use of two rigid pins and a A-shaped notch. The pins were placed a few inches apart on the lower edge of the rebate of the printing frame, and the notch is on the movable inner frame to which the negative is affixed, and fits over one of the pins, while a similar notch is provided on the wooden back to which the printing paper is temporarily fastened. The inner frame is made of thin aluminium, cut like a passe-partout mount, and the negative is fastened to it temporarily by strips of Alcock's porous plaster—a material which clings to both surfaces with great tenacity, while it strips off readily without parting with any of its adhesive composition. Mr. Cherrill may be congratulated upon this discovery alone, which should be valuable for various other photographic operations.

The wooden back of the frame is in one piece, without the custo-

mary hinge, and is covered with felt, on the top of which is a piece of waterproof sheeting. On this is smeared some indiarubber solution, slightly diluted, and it is found that the back of the printing paper can be firmly attached to this adhesive surface, and can be easily removed when the printing process is complete. As an example of the perfect manner in which registration was preserved, the lecturer handed round a print from a negative upon which three tiny scratches had purposely been made. This print was the result of thirty different exposures in three different frames, but the fine scratches were quite sharp and distinct.

We will now consider some of the uses to which Mr. Cherrill proposes to put this new printing appliance, which he abundantly illustrated by specimen prints handed round for examination.

Modern lenses, he pointed out, give almost painful sharpness of definition, and where it is desired to reduce this so as to obtain a more "pictorial" effect a sheet of celluloid can be interposed between negative and paper during part of the exposure, and subsequently removed, the remainder of the exposure being conducted while the negative is in actual contact with the printing surface. Several different thicknesses of celluloid can be thus used on one print. Or a celluloid sheet bearing a grained image can be interposed—e.g., a canvas grain or a paper grain (examples of each were shown). Or if it be desired to increase diffusion in certain parts of the negative, paper shields can be employed in conjunction with the celluloid mask.

The lecturer next dealt with the control of values, and he made a distinction between what he called "fixed control" and "progressive control." The first is secured by the old method of darkening parts of the negative by backing it with paper and working upon the paper with stump and chalk, and he considered it very difficult by such means to get the exact result aimed at. In "progressive control" he uses a sheet of celluloid to interpose between negative and print, and paints upon its surface with burnt sienna water-colour the parts to be made lighter. This is inserted as a shield during part of the exposure, with the result that the painted parts are blocked out. Then the shield is removed, and printing is completed without it.

For darkening certain parts of a picture the reverse operation is necessary. In this case he employs a sheet of gelatine which has been flowed over with a stained collodion. When dry, the parts to be treated are scraped away. These parts then get a start in the printing, and of course they come out darker in the end. In certain cases lines can be etched out of the coloured surface with a needle, so as to get small accentuated shadows. It is evident that this work could not be done without a perfect system of registration. The lecturer also advocated the employment in certain cases of a positive made by photographic means on celluloid to be used in conjunction with the negative in printing—a suggestion which has often before been made and put in practice. He claims for these various methods of control printing that, although they consume some time, they do away with the necessity of that elaborate retouching which, from the professional point of view, is very costly.

In concluding his paper, Mr. Cherrill pointed out that the new frame would be found very valuable in all kinds of combination printing, that it would be welcomed by gum bichromate workers, and, lastly, that, because of its true registration, it would especially appeal to those who worked the trichromatic method of printing. He trusted that its use would help to raise photography to a higher plane of excellence than it had yet attained, by removing several of the difficulties which beset the pictorial worker.

Mr. Horsley Hinton, who occupied the chair, said that he considered that the frame offered a very ingenious and simple method of helping photographers in their printing operations, and alluded to his own method of dealing with large negatives by printing them on a drawing-board and securing registration by the use of pins. He thought that the new frame would prove very serviceable for smaller negatives. Various questions were raised by other speakers, in reply to whom Mr. Cherrill said that the printing work on the interposed sheet of celluloid was done while the negative rested on a desk furnished at its lower edge with the necessary registration pins. The frame would, he hoped, be soon obtainable commercially.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.
FEBRUARY 4.—Mr. Anthony in the chair. The Hon. Secretary read

a letter from Mr. W. D. Welford, offering a set of lantern-slide portraits of photographic celebrities, taken at the various conventions, to the Association, an offer which was gratefully accepted. Mr. Gotz read a paper on the decimal and metric system, illustrating his remarks with models of how the metric system admits of comparison between solid and liquid weights and measurements, on remarkable exhibit being a set of weights at 1s. 3d. Mr. Haddon gave the historical method of fixing the English units, and endorsed all the lecturer's arguments in favour of the metric system. Mr. Child Bayley was opposed to any such change. Mr. Drage was also opposed to change, and thought that Britain and America were strong enough to get along with a system of their own.

CROYDON CAMERA CLUB.

FOR some little time past it has been generally felt that disturbances were in the air, and something in the nature of a spirit of division was arising between the members. The first open indication of this was shown at the annual meeting, when, as already recorded, a contested election for the presidency took place, Mr. Hector Maclean, F.R.P.S., being re-elected. This meeting was adjourned to January 27th to further consider other matters which could not be dealt with at the time, and on its resumption, to say the least, very plain speaking was indulged in, the principal target being the president himself. A resolution was also carried to the effect that no member should in future hold the office of president for more than two consecutive years.

On Wednesday, the 3rd inst., Mr. F. W. Sticks gave a capital demonstration on transparencies for enlarged negatives, and as this is to be followed by instructions as to how to make the latter, both can be conveniently dealt with later. Prior to the lecture, Mr. Maclean arose and read a written statement, in which he made a brisk counter-attack upon his opponents, and announced his intention of resigning the presidency forthwith. He also laid down certain alternative and stringent conditions which would have to be carried into effect before he would entertain any suggestion of resuming his presidential duties. Mr. Maclean then left the meeting, his place being taken by the vice-chairman, Mr. E. A. Salt, who alluded to the great services rendered to the club by Mr. Maclean, extending over a period of thirteen years. He regretted his resignation, and particularly the circumstances which had led up to it, but thought the conditions laid down were most ill-advised. He had, therefore, no option but to entirely dissociate himself from them, and finally urged all members to forget past differences and to pull together for the good of the club. Other speakers followed, and the line taken up by all clearly indicated this would be so, and an "entente cordiale" in future would reign. It also became plainly evident that the next president, whoever he may be, will have no lack of energetic and willing helpers.

The fifth annual exhibition of the Cripplelegate Photographic Society will be held at Cripplelegate Institute, Golden Lane, E.C., from February 29th to March 3rd, opening at 6 p.m. on the 29th until 10 p.m., and 1 to 10 p.m. on the other days. An attractive programme is being arranged, including practical demonstrations of enlarging by artificial light, platinotype and carbon processes, etc., and the latest novelties of the various manufacturers will be on show. By special request the closing of entries for pictures has been postponed until February 19th, and all entry forms must be in the hands of the hon. secretary, Mr. George H. Depledge, 17, Hazeldene Road, Goodmayes, Chadwell, Essex, by this date. Pictures must be sent to Cripplelegate Institute as in previous years.

A "GRAND Kodak" Exhibition will be held on February 15, 16, 17, 18, 19, at the Public Hall, Croydon. The exhibits will comprise pictorial enlargements, cinematograph and lantern displays, novel and ingenious apparatus, technical exhibits, and continuous demonstrations illustrating the simplicity of modern photography. It will be open from 10 a.m. to 10 p.m. daily, and bright and attractive lantern lectures will be delivered at 4 p.m. and 9 p.m. by Dr. Dixon. Admission will be free, and complimentary tickets and full particulars can be obtained from all local Kodak dealers, or from Kodak, Ltd., 41-43, Clerkenwell Road, E.C. The Exhibition will be opened at 7.45 on Monday evening, February 15th, by Sir F. T. Edridge.

Commercial & Legal Intelligence

ELL'S PHOTO COMPANY, LIMITED.—This company has been registered with a capital of £2,000 in £1 shares. Object, to carry on business of publishers, photographers, stationers, photographic general printers, and engravers, etc. No initial public issue. First directors (to number not less than two nor more than five) T. E. H. Bullen, chairman and managing director, and Mrs. D. Bullen. Qualification, £10. Remuneration as fixed by the company.

At the West London Police Court, on February 2nd, Arthur Copus, a baker's assistant, living at 46, Percy Road, Shepherd's Bush, was charged with being in the unlawful possession of a camera and photographic accessories. Mr. Oswald Hanson defended. Detective-Sergeant Nurse stated that the camera was advertised for sale in the "Exchange and Mart," and the accused, it was alleged, was giving the advertisement in the name of "J. Youngly," giving an address at 123, Approach Bridge, Shepherd's Bush, offered to hand a concertina in exchange. The advertiser despatched the camera, and the Detective-Sergeant, who had received certain information, kept watch, and saw the prisoner call at the address at Approach Bridge, a tobacconist's shop, and emerge with a box containing the camera. Subsequently, the officer went to the prisoner's lodgings, but could find no concertina. The Magistrate granted a warrant, offering to accept bail for his appearance.

CHARLES JOSEPH JONES, Photographer, 75, Essex Road, Islington, N.—The public examination of the above-named debtor took place at the London Bankruptcy Court on Thursday, last week, before Mr. Registrar Hope. In reply to questions put by the Official Receiver, Mr. Chapman, the debtor stated that he commenced business as a photographer at 75, Essex Road, Islington, in 1892, with a capital of £50 of his own. He carried on the business with fair success until two years ago, when, owing to his inability to attend his customers, through a long and severe illness, the business failed. His expenses had exceeded his profits for some time past, owing to his being compelled to draw heavier than usual through illness of himself and family. He was pressed by creditors about five months ago, and he then realised that his assets were insufficient to pay his debts. The petitioning creditor, Mr. Ketch, obtained judgment against him, and filed the petition in bankruptcy next witness. He offered his creditors a composition of 10s. in the £, but they refused to accept it. He alleged his failure to have been caused through loss on trading during the past two years. He should think he made a profit of £300 in 1900, but in 1901, 1902, 1903, he did not make more than about £150 per annum. His expenses exceeded that amount, as his medical expenses came to about £100, and then he had to employ a competent assistant to manage the business whilst he was ill. He should think that during the last three years he had overdrawn his profits by about £500. It would include medical expenses and extra assistance. He also made a loss through taking a house in Canonbury Park. He took the house for business purposes, but after he had taken it, he was told that he must not carry on business there. The agent to the landlord told him that he might carry on his photographic business there, but shortly afterwards the landlord died, and he was stopped. The landlord, as a matter of fact, died before he took possession of the premises. He was not now liable for the rent of those premises, as he had been relet. When he found he could not carry on business as a photographer there, he used the place for printing purposes. He was liable for two quarters' rent there, and there was no claim for dilapidations. He had disclosed all his assets, and had not concealed anything. He was not entitled to any reversion in any property of that kind. He received certain property under his father's will in 1901. In that year his father died, leaving certain leasehold and freehold property, to which he was entitled. The property was mortgaged for £500 by him, of which he retained £200. He handed £50 to his brother, and the remaining £150 went to pay law costs, and other expenses. Afterwards he handed the equity in the property to his mother. He did that because he knew that his father was carrying out his father's wishes. Questioned by Mr. Strouts,

who appeared on behalf of the petitioning creditor, debtor said he formerly used three cameras in his business. He did not hire them, as they were his own property. He only had one at the present time, the remaining two having been pledged. He pledged them about fourteen months ago, and gave the name of the pawnbroker to the Official Receiver. The value of the camera he still had was about £4. That was about the price it would fetch under the hammer. The reason he was still using it was because his wife had purchased it of the Official Receiver. His wife was also paying the rent of the premises at which he was now carrying on business. She had obtained the money from her friends. The electric light apparatus that he used in his business was obtained of Messrs. Still, of Hatton Garden. He obtained it on the hire system. The price was to be £50. He had paid £38 on account, so that there was still £12 outstanding. The examination was eventually ordered to be closed.

News and Notes.

ERRATUM.—In Messrs. The Metotype Company's advertisement which appeared in our issue of February 5th, the word "Pure" should have preceded the word "Aluminium" only.

MR. THOMAS BEDDING, F.R.P.S., Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*, is to deliver a lecture at Staines on Thursday, February 25th, the subject being "Animated Photography in Theory and Practice."

THE ST. LOUIS EXPOSITION.—Amongst European savants who have accepted invitations to deliver addresses at the International Congress of Arts and Science at the St. Louis Exhibition are the following:—In Department 9 (Physics)—Professor Dewar, the Royal Institution, London; M. Becquerel, Member of the Institute of France. In Department 10 (Chemistry)—Professor Moissan, Paris; Professor Fittig, Strassburg; Professor Van t'Hoff, Berlin; Professor Kossel, Heidelberg; Professor Mendeleeff, Technical School, St. Petersburg.

A CORRESPONDENT writes:—I am sorry that your kindness in sending me the *JOURNAL ALMANAC* has remained so long unacknowledged, but it has been lying here waiting my return from the U.S.A., and has only just come into my hands. I am much obliged for it. It is almost big enough to satisfy Yankee requirements! By the way, I was entertained one evening in Boston by the president of the ——— Camera Club, who discoursed in a piquant manner on the Ho'land Day School. He ended by saying, "I do think that British journal of yours is a dandy paper; its remarks on the American school have pleased us here immensely!"

THE first annual dinner of the Cardiff Windsor Amateur Photographic Society was held at Barry's Hotel, Cardiff, on Thursday, February 4th, Mr. Harold Lloyd presiding, when nearly one hundred members and friends sat down to dinner. The chairman in his opening remarks spoke most favourably of this Society, which, formed in November last, has already made a name in the local photographic world. He himself was surprised at the progress made, and he made up his mind on the spot to become an amateur photographer and join the Society. Also for the sake of further encouraging the Society he intimated his desire to present to the Society a challenge cup to be competed for.

RUSKIN EXHIBITION at Manchester.—An exhibition is to be held at the Manchester City Art Gallery, opening on March 23 next and closing on May 14, of pictures and other works of art illustrating the life and work of Ruskin, including the Early Italian painters, Turner, the Pre-Raphaelite Brotherhood, and also Ruskin letters and manuscripts. The committee will be glad to hear from anyone possessing such works and willing to lend them for the exhibition. Early communication from those who are willing to help the committee in this way, addressed to the curator at the Art Gallery, is desirable. The exhibition is being organised for the committee by Mr. W. G. Collingwood.

DEATH of Lady Pullar.—Members of the Photographic Convention of the United Kingdom who were at the Perth meeting in July

last will hear with regret of the death of Lady Pullar, which occurred at Tayside on the 3rd inst., and sincerely sympathise with Sir Robert and his family. Although Lady Pullar's illness has for some months been regarded as serious, it was hoped that the constant care of those about her would enable her to rally, and continue to help her husband in the many good works in which he is engaged. It has, however, been willed otherwise, and the people of the city of Perth have lost a kind and sympathetic friend. The funeral, which was a public one, took place at Welshhill Cemetery on Saturday last, and was very largely attended. Among the flowers was a large anchor sent by the hon. general secretary (Mr. F. A. Bridge) on behalf of the members of the P.C.U.K. Lady Pullar was in her seventy-fifth year.

"As Others See Us"—Why is it that men, otherwise altogether above reproach, will, whenever they get, or think they get, a chance, take a sly dig at their American brethren? The latest offender in this direction that I have come across is in the old, reliable *BRITISH JOURNAL OF PHOTOGRAPHY*, where the editor, in telling of Denmark and the Faroe Islands having entered into the Berne Convention, so as to get and give the benefits of the Copyright Union, adds: "America has always held aloof from this (and more's the pity, say I), with the result that English works are pirated through thick and thin in the United States, as British and Continental publishers know to their cost;" and then he rather ungraciously adds: "Of course, American works can be reproduced here, but then there are comparatively few that English publishers would care to copy." And on another page, after telling of an unusually large enlargement that has been made in Germany, a copy of which will be sent to the St. Louis Exhibition, he adds, less ungraciously, of course, but looking as if it carried with it something like a sneer, "Will the Yankees be eclipsed?"—*American Amateur Photographer*.

THE Late Mr. W. L. Thomas.—In response to the desire expressed by the many friends and admirers of the late Mr. W. L. Thomas, the founder of the "Graphic" and "Daily Graphic," that some fitting monument should be raised to the memory of one who contributed so largely to the advancement and elevation of the illustrated Press, an influential committee has been formed for this purpose. It is proposed to place in the Church of St. Clement Danes, in the Strand, the vicinity of his labours for the past thirty years, a memorial in the form of a portrait in bronze relief or a marble tablet with a suitable inscription. Sir James Blyth, 33, Portland Place, W., and Mr. Luke Fildes, R.A., 11, Melbury Road, Kensington, W., are the hon. treasurer and hon. secretary respectively, and will gladly receive and acknowledge all subscriptions. The following gentlemen form the committee:—Sir William Agnew, Sir John Aird, M.P., Sir Lawrence Alma-Tadema, R.A., Lord Avebury, Major-General Baden-Powell, C.B., Mr. T. J. Barratt, Sir James Blyth, Sir Edward Clarke, K.C., Mr. Luke Fildes, R.A., Mr. W. S. Gilbert, Lord Glenesk, Mr. Augustus Helder, M.P., Mr. H. Rider Haggard, Sir William Ingram, Mr. C. E. Jermyingham, Sir Harry Johnston, Sir Edward J. Poynter, P.R.A., Mr. V. C. Prinsep, R.A., Sir Cuthbert Quilter, M.P., Mr. H. C. Richards, K.C., M.P., Admiral Sir E. H. Seymour, the Hon. W. F. D. Smith, M.P., Mr. Gordon Thomson, Sir Henry Trueman Wood, and Mr. Henry Woods, R.A.

GLASS and Glass Bottles.—At a recent meeting of the Poor-Law Dispensers' Association Mr. G. W. Lindsay, M.P.S., read a paper on "Glass and Glass Bottles." The ancient history of glass was first dealt with, from Egyptian and Roman times. Afterwards Venice, Germany, and France were pre-eminent respectively in glass manufacture. It was not until the sixteenth century that glass was manufactured in Britain. Before 1773 all the plate-glass was imported from France; but British manufactures were now superior to any other nation in Europe. Glass is formed by the fusion of silicious matter, such as powdered flint or fine sand, together with some alkali, alkaline earth, salt, or metallic oxide. Five kinds are usually recognised in commerce—(1) Bottle, or coarse green glass; (2) broad spread, or sheet window glass; (3) crown, or the best window glass; (4) plate-glass, or glass of pure soda; (5) flint glass, or glass of lead; and coloured glass may be mentioned as a sixth kind. The modus operandi of the glass or bottle blower may be shortly summed up as follows:—The melted glass, which has already been calcined in

the "fritting furnace," is transferred on iron shovels to the working furnace, where, under the action of great heat, it becomes fused and fit for being blown. A long hollow iron rod, about 5ft. in length, is taken and dipped into the pot. A sufficiency having been taken up, the workman blows into the other end of the tube, rolls it up and fro on a smooth slab, then slips it into a mould, still blowing through the rod; after which other deft operations form the neck and rim of the bottle, and it is then carried off on an iron rod to the annealing furnace, from which, when cooled down, it emerges as a perfect bottle.

ACTINIC Quality of Sky-Light.—Mr. Gavin J. Burns has recently published the results of some experiments made by him in order to determine the relative actinic qualities—not intensities—of the light received from the star-lit sky near the zenith on a clear night, moonlight, of sunlight, and of the light received from the zenith during the daytime. With ordinary, bright light-sources the usual method of procedure in determining the ratio of actinic to non-actinic rays (i.e., the actinic quality) in the total radiation is to analyse the latter in detail, spectroscopically; but in the experiments performed by Mr. Burns the total radiations were far too faint for the application of this method. He therefore divided the spectrum generally into two parts, actinic and non-actinic, and in order to obtain comparative results used layers of two liquids as screens, the first a solution of bichromate of potash, which totally absorbed the blue, violet, and ultra-violet rays; the second a solution of methyl-violet which absorbed the orange, yellow, and green. In each experiment a layer of known absorptive effect was placed between the photographic plate (Edwards's isochromatic) and the light source. The plate was then exposed to the light for a known period and developed, and then the various results were reduced to standard conditions and compared. From the results thus obtained Mr. Burns concludes that the actinic quality of the light which reaches us from the zenith sky by night, when the sun is at least 18deg. below the horizon, is greater than that of moonlight from the moon on the meridian, or sunlight when the sun has an altitude not greater than 36deg. It is also greater than the average value for the light of the blue, cloudless sky by day. On the other hand, the observations give no information as to the real relative actinic qualities of sunlight and skylight, for observations of both sources at equal altitudes must be made to determine this ratio (*British Astronomical Association "Journal,"* vol. xiv., No. 2).—Reprinted from "Nature."

RAPID Photographic Manipulation for Newspaper Illustration.—An example of how the latest apparatus for quick photographic manipulation can be used to advantage in a novel way was demonstrated last summer by a representative of the "Newark Evening News." He was commissioned, writes the "Scientific American," to be stationed on the revenue cutter Gresham, to photograph the international yacht race on August 25th, 1903, the second day of the race. He took with him a Kodak camera, a Kodak developing machine, the material necessary for developing film negatives, a number of carrier pigeons. The yachts were photographed as they crossed the starting line at 11 o'clock a.m. Immediately after taking the picture he placed the developing machine, containing the developer, upon a table on the deck of the vessel, and in broad daylight developed and fixed the roll of exposed film. This was completed in about ten minutes. The finished film negative was hurriedly dried, then rolled up in small compass, and securely wired to a carrier pigeon under the tail, where it would in no way impede its flight. The pigeon was then released, and in exactly an hour and a half arrived at its loft in Newark, N.J. The negative film was found upon it in good condition, and was at once removed forthwith to the newspaper office, where a print was made, and by 3.48 p.m. a half-tone plate was completed by the usual half-tone process, placed on the press, and a few minutes later the paper appeared containing a picture of the morning's yacht races. It was quite a novel idea to utilise the carrier pigeon for transporting photographic films for purposes of quick reproduction, and, in its way, is more positive than wireless telegraphy. We believe during the siege of Paris in 1870 letters reduced by photography down to extremely small size were transported by carrier pigeons to the outside world, and then enlarged by a lantern upon a screen large enough to read. But that was prior to the days of rapid photography or dry-plate or film machine daylight development.

Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

A CORRECTION.

To the Editors.

Gentlemen,—I shall feel obliged if you will kindly correct a slight error in your report of my lecture at the Camera Club upon the photography of some electrical phenomena. You speak of a single electrical discharge as occupying about 1-1,000,000 of a second. I said it was about 1-20,000 part of a second; or, in other words, about 500 times the amount your report states.—Yours faithfully,
GEO. H. RODMAN.

Green Gate House, East Sheen, S.W.
February 8th.

ORTHOCHROMATIC PHOTOGRAPHY.

To the Editors.

Gentlemen.—Messrs. Newton and Bull have opened up an entirely new subject, when they pointed to my "inconsistent statements," and this probably to divert attention from the fact that the original speed ratio of 21:480, as given in their paper to the B.S., has now been corrected to a ratio of 5:9. However, I may point out that I have taken the precaution in each of my letters to make a definite statement, but to say that the speed ratio is practically 1:1; and again, after reading the full particulars of tests and repeating my own with incandescent gaslight—tests which have nothing in common with those Mr. Newton speaks of—stated that I find the ratio to be practically 1:2. Was it "effrontery" to state that this ratio is confirmed by Messrs. Newton and Bull's corrected ratio of 5:9?

Using the not scientific expression of "practically," I expected that Newton and Bull to be sufficiently familiar with collodion emulsion as to know that to make a definite statement as to the comparative speed of such emulsion—especially if sensitised with aniline compounds—is an utter impossibility, and that a fair latitude must be given, which may permit a doubling or trebling of a ratio, never a correction of a ratio of 21:480 to that of 5:9, whatever the illuminant may be.

The latitude I speak of is permissible, as age of the emulsion and other conditions cause variations of speed.

A similar concession must be granted to the ratio of trichromatic filters adjusted for such emulsions.

Professor von Hübl has obliged me by making practical speed-tests, with special reference to this discussion, and give the ratio as 1:2 if electric light is used. He further states that if a weak silver is used, the speed of the ethyl violet sensitized emulsion is reduced.

I have also communicated with Dr. E. Albert, who expresses surprise at Messrs. Newton and Bull's speed tests, referring to unsensitized and "A" sensitized emulsion (eosine silver), which, he says, is sufficiently contradicted in Professor Dr. Vogel's Handbook of Photography, Part III., page 183, and supposes that the statements are based on some error.

Professor Dr. Valenta's letter points to a forthcoming publication early issue of the "Photographic Correspondence," which will have some bearing on this matter.

The rest of Mr. Newton's letter is of a personal character, and irrelevant to the subject.—Yours obediently,

HENRY O. KLEIN.

London, February 8th.

OLD LENSES.

To the Editors.

Gentlemen,—The excellent "Ex Cathedra" columns of a recent issue contained a note on the difficulty of securing a representative selection of photographic lenses, as inaugurated by Dr. Rohr for the R.P.S. I am in possession of a very primitive and massive landscape lens, with a peculiar circular stop, fitting in a

small projecting diaphragm tube, with a spring ring and a brass cap. The objective is not scratched or damaged, beyond the natural effect of wear and tear. The mount is slightly corroded, but altogether the lens is in excellent preservation. With your permission, I will shortly publish details of maker's name, focal length, and other particulars.

I should be happy to afford your readers an opportunity of viewing this old instrument, by arranging a tour of it to photographic, optical, and other scientific societies, whose secretaries or responsible officers will communicate with me. Other readers may obtain cabinet photographs of it from me. After the tour I shall ask the Council of the R.P.S. to do me the honour of accepting it for their collection.—Yours faithfully,
FRED. W. EDWARDS.

Swadlincote, near Burton-on-Trent.

THE BRENTFORD EXHIBITION.

To the Editors.

Gentlemen,—Might I ask you to make it known through the medium of your paper that there has been an unfortunate delay in the preparation of entry forms for the forthcoming Brentford Exhibition; but some are now ready, and can be had on application to the Exhibition Secretary, 7, Clifden Road, Brentford, Middlesex. The Exhibition will be held in the Baths Hall, Brentford, on March 15th, 16th, and 17th. There will be five classes in the open section, and the awards will take the form of specially designed plaques in silver-gilt, silver, and bronze. The judges are Messrs. R. Child Bayley, R. W. Craigie, and J. C. S. Mummery. The society undertakes to collect exhibits free of cost from the South London Exhibition, and same can also be sent on to Croydon Exhibition free. Entries close March 3rd.—Yours, etc.,

FRANK H. READ, Exhibition Secretary.

Ferndale, Clifton Road, Brentford,
February 6th.

At the next Royal Photographic Society lantern meeting, on Tuesday, February 16, at 66, Russell Square, at 8 p.m., the affiliation competition slides will be shown.

The Stereoscopic Society is entering upon its twelfth year. Since its foundation it has circulated and divided among its members from 350 to 400 slides per annum. One or two more members will be heartily welcomed. The joining fee is 1s. 6d., and an annual subscription of 2s. The secretary, Mr. B. Diveri, Huntly, N.B., will be pleased to furnish further particulars upon application.

GLASGOW Southern Photographic Association.—Messrs. Archibald Cochrane, J. W. Eadie, and Tom McEwan, R.S.W., have consented to act as the judges for the third annual open exhibition of the Association to be held in the club rooms, 1, Eglinton Lane, Glasgow, from 22nd March to 5th April. Entries close on 1st March. A copy of the prospectus, which is now ready, may be had on application to the honorary secretary, 28, Bank Street, Hillhead, Glasgow.

LONDON County Council School of Photo-Engraving and Lithography, 6, Bolt Court, Fleet Street, E.C.—A course of seven lecture demonstrations on half-tone work will be given by the Principal on every Thursday evening, from February 11th to March 24th inclusive, commencing at 8 o'clock. Syllabus.—February 11th.—Introductory. Half-tone: Its meaning and object. Various methods of obtaining typographic blocks having half-tones. The original: Its nature and treatment. February 18th.—The negative. Apparatus required, types of cameras and lenses, screens, cross-line, chess-board, grained, metzograph. Methods of holding the screen, and its adjustment. February 25th.—The negative. Principles governing exposure. Optical considerations in the formation of the half-tone dot. Finishing the negative. Respective advantages and disadvantages of wet collodion, collodion emulsion, and gelatine dry plates. March 3rd.—The printing on to metal, fishglue and dry enamel processes. Rough etching and fine etching. March 10th.—Finishing, mounting, and proving. Machinery required, choice of papers, etc. March 17th and 24th.—The application of typographic methods to colour work. Tri-colour, extra colours. Transfers for surface methods—e.g., lithography, algraphy. Admission is free to students of the school; to others, ticket for the course, 2s. 6d.; single lectures, 1s.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

C. A. Pinnock, 423A, High Street, Cheltenham. Photograph entitled 'Pile Fishing on the Thames.'

J. Bates, 113, North Montrose Street, Glasgow. Photograph of Band of the R.M.A.

T. G.—The address of the company is we believe, Liverpool.

M. D.—We know nothing of the person named. The only advice we can give is to sue in the County Court for the balance, as the lessons have not been given.

CHARGE FOR NEGATIVES.—A. S. MARSHALL says: "I have an order from a gentleman to take some views ($\frac{1}{2}$ -plate size), which he is going to copyright for pictorial postcards. Would you kindly inform me what is the usual charge per negative?" In reply: There is no "usual" charge for such work. Every one fixes his own price for his work, and you had better do the same. You can better assess its value than anyone else.

RETOUCHING.—"G. H. W." writes: "Kindly let me know (1) your opinion of enclosed retouching specimens; (2) what wages ought a man to get as a retoucher and operator, taking the enclosed specimens as the average work?" In reply: (1) The work is creditable; but in one or two instances there is a little alteration in the likeness. (2) If this is your average work we should say you ought to receive a salary of from two guineas to fifty shillings a week.

BLEACHED LAC.—"E. E. H." says: "Some little time ago you spoke of some bleached shellac that you found good and soluble. Can you say where I could get a small quantity, say 1lb.? I have had several lots, but stale and insoluble. My agent here has not been able to procure me the Year Book this year; he says his agent in London informs him that it will not be published till May?" In reply: There should be no difficulty in obtaining good bleached lac. Messrs. C. W. Waters and Co., 72, Great Eastern Street, E.C.1, are lac bleachers. "The British Journal Almanac" was published in December last.

PROCESS BLOCKS.—"W. C. E." says: "Enclosed please find cover of magazine with three blocks of churches. Will you kindly tell me why they are faint? The printer tells me they will not take any more ink. Are the blocks at fault, the paper or the ink? I got the blocks made for our vicar, and the firm who produced them are reckoned first-class. The vicar is not at all satisfied, and I should be glad if you would say where the fault is." In reply: We should advise you to place the blocks in the hands of another printer and see what he can do with them. We may tell you however that the paper is not well suited for printing fine blocks upon. The best results must not be expected on such paper.

PICTURE FRAME MAKING.—"INQUIRER" asks: "Would you kindly inform me if you know of any firm that makes a speciality of picture framing apparatus, such as cramps, mitre boards, etc., or if such things as these are generally obtained from an ironmonger and tool dealer; also if there is any book published on the making of picture frames? Could you furnish me with one or two addresses where picture mouldings can be obtained wholesale?" In reply: All the necessary appliances for picture frame making are supplied by good tool makers, such as Buck's in the Tottenham Court Road, Messrs. Dawbarn and Ward, Farringdon Road, issue a book on the subject. There are

many firms that supply mouldings wholesale. Consult a "Post Office Directory."

THE VERANT.—A. G. BEAUNIRNE (Chicago) writes: "I was very much interested in the reference made to the experiments of Dr. Moritz von Rohr with stereoscopic photography in the introduction to the last 'Almanac.' I hope you will permit me for troubling you about the matter, but I should be very glad to know more about Dr. von Rohr's experiments; and whether he has reached any satisfactory results, and should consider myself under great obligations to you if you could let me know whether I could get further information. I am interested in photography, and especially stereoscopic photography, as an amateur, and have read your 'Almanac' for a number of years with interest and profit?" In reply: We reprinted Dr. von Rohr's paper in this JOURNAL of January 8th, 1904.

INCANDESCENT BURNERS.—"MORE LIGHT" says: "In your issue of August 28th, 1903, page 684, re 'The Gas Mantle,' you announced a new portable lamp. Will you kindly answer as to: (1) Whether the above lamp is yet on the market, price, and whether the company have agents in or near London. (2) Whether suitable for the magic lantern, and if so the power of light as compared with a three wick oil lamp. (3) Whether the lamp invented by Mr. Birt Acres is on the market, and refer to the one in which a greater pressure of gas is obtained. If so, price, etc.?" In reply: (1) We cannot say. Why not write to the patentees, whose address is given in the article. (2) We have had no opportunity of comparing the lights. (3) We cannot say. Here again, why not inquire of the inventors direct for the desired information?

SPOILT NEGATIVES.—J. SMITH writes: "I will be most thankful you will help me in getting out of the present trouble I am in. I have had a lot of good negatives given to me to print specimens, and before I got two prints of each they all were filled with yellow spots, most of them through the film; some were on the surface—silver stains. I expect I will be responsible for them as they were good when I had them printed. If you will kindly tell me what to do to restore them I will indeed be thankful to you?" In reply: So far as we can judge by merely looking at the prints we should say that you have used damp paper in printing from the negatives and so stained them. If the stains go through the films it is doubtful if they can be removed; but that, of course, we cannot express no decided opinion upon, as we have not seen the negatives. Try soaking them in a new solution of hyposulphite of soda for some hours.

A VERDICT of suicide while temporarily insane was returned at coroner's inquest at Marylebone last week into the death of a colour printer named Beck, who died from cyanide of potassium poisoning. He had often threatened to take his life, and after reading the accounts of Mr. Whitaker Wright's death remarked that death by cyanide of potassium appeared to be easy.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Rathenower Optical Works appear to have suffered an injustice rendered possible by the state of the German law of Trade Marks. A three lens system corrected only for colour and spherical aberration hitherto been sold by the Rathenower Company under the name of Perioplanat. This name was not registered, but the Hamburg firm, Dr. Lüttke and Amdt, has given the same name to a lens not corrected for colour, and registered notwithstanding the fact that it was previously used by the Rathenower Company. The German Patent Office has allowed the objection to this appropriation of a name used by another firm, and the appropriators have forbidden the use of the name by customers of the Rathenower Company. The hitherto users are thus compelled to find a different name for their lens, and they are now mulcted of the expense of making known the change. The Rathenower lens will henceforward be called the "Metaplanat." This is evidently a wrong forged for the unwary by the German Government.

* * *

Impressionism The gentleman who writes the "Science of Starland." Notes in the "Daily Telegraph" tells readers that a discussion is now going on in astronomical circles touching the proper use of photography

in the astronomical observatory, and he very rightly says that the primary object of practical astronomy is to leave faithful records of things as they are for the benefit of future generations. It seems, however, that the impressionist is making his presence felt even in these pictures of starland which, to be of real service, should be maps of the heavens, and nothing more. But when the writer tries to explain how the improved artistic appearance is brought about he is as nebulous as some of the orbs to which he refers. He informs us, "that by skilful arrangements of lighting and by local reduction more attractive copies of nebulae and other celestial objects can be made than by mere contact printing," and that "the query arises whether these copies are true representations of the objects depicted." We confess that we do not know what this means, for the stars and nebulae are photographed by their own light. No arrangement of their lighting could be possible, and if it were neither such an arrangement nor "local reduction" could possibly take the place of printing. Again, he says that "a simply developed negative may show more detail than the eye can see with the telescope, but a contact print made from this may show a great deal less, and, therefore, such a print is not more true than a manipulated copy." We fail once more to understand the true inwardness of this remarkable paragraph. The writer is evidently not a practical photographer, and he would do well to leave such matters to the compiler of the photographic column in the same journal. *Ne sutor ultra crepidam.* The last-named would then have an opportunity of escaping for a time from the vagaries of bromide paper, with which he endeavours so perseveringly to interest his readers.

* * *

Hints to German Exporters.

Under this title a German paper, "Photographische Industrie," publishes two letters from well-known persons in Italy and Russia "La Revue Mensuelle du Commerce et de l'Industrie Photographique," giving some account of the wants of these countries in the photographic trade. In Italy French plates appear to be the favourites, but the "Barnet" plate seems to be gaining a foothold. Most of the silver paper is of English origin, and Kodak has the larger part of the trade. Carbon tissues are supplied by the Autotype Co. and the French firm, Lamy. German cameras predominate, because they are cheap and no attention is given to quality. Developers and sundries are mostly of German origin. Although Italians correspond with more facility in French than German, this fact appears to be neglected by the former, who might by such an advantage obtain the first place in supplying Italian markets. Concerning Russia, it must be granted that Germany has most of the trade, but this does not depend upon quality of the goods.

France does a good business there, but principally through agents. French lenses enjoy much favour, for their cheapness and good quality, but not much is known of their origin either by amateurs or dealers. The only way to acquire the trade is by opening branches in the large centres, as the risks are too great, and the good firms too few. Another means is by demonstrations at the photographic societies. The Russian public is tired of German goods, the cheapness of which is more apparent than real. English and American firms have discovered this, and are taking advantage of it. Apart from Kodak, a much greater number of English and American patterns of apparatus were observable in retailers' windows than ever before. If French manufacturers are apathetic, so also are Russian dealers. They object to trouble, and are used to being called upon and tempted by offers. If these letters correctly represent the state of the photographic trade in Italy and Russia, they point the way to business for enterprising English firms. English plates, like English papers, should rule the market, and English cameras should find their way into the hands of everyone who takes a serious interest in photography. We even venture to say that the best of our English hand cameras, if pushed with intelligence in Germany, would soon make headway and find a ready sale among amateurs, who look more to usefulness than price.

* * *

Gas. The name of Sir William Abney as a member of the Committee recently appointed by the Board of Trade to consider various matters in connection with the gas-supply of the Metropolis, is a guarantee that the interests of consumers will be well looked after. One of the chief points to be considered is the advisability of lowering the candle-power, so as to save cost both to manufacturers and users. The importance of this will, perhaps, not be appreciated until it is remembered that quite eight-tenths of the gas made is employed for heating and cooking, for motive power, and for incandescent mantles. For none of these purposes is a luminous gas required, the blue flame being all that is necessary. Hundreds of thousands of pounds are, therefore, being annually expended upon enriching gas that needs no treatment of the kind. If the use of mantles were made compulsory, and the old burners were thrown away, a gas costing a few pence instead of shillings per thousand feet would answer every purpose. But it is clear that the gas-mantle, largely as it is at present employed, will never be universally adopted until it is improved. We want something much less perishable, a mantle which can stand a little knocking about without injury. It represents a very beautiful adaptation of scientific research to common uses, but it is almost as delicate as a cobweb, and a good sneeze in its near neighbourhood is quite sufficient to annihilate it. Surely it should not be impossible to make a mantle of less delicate structure, with a dash of, say, flint in its composition, so that it can be handled by the roughest of fingers. We might also suggest, while improvements are under consideration, that a mantle might be introduced of smaller volume and giving a far lower candle-power with a corresponding reduction in the gas consumption. The man who has been content with a ten or twelve candle-power gas flame for years does not want the tremendous glare of the ordinary mantle, which, we suppose, represents something like seventy candles. A lesser light, say, of twenty candles with a gas consumption of about one foot per hour would suit his modest wants and his pocket much better. Let those of inventive minds, therefore, set their wits to work to produce a little fixing of highly refractory material, with the incandescent qualities of the present mantles, but

without their extreme fragility, which can be sold for a penny apiece, and he will earn the gratitude of his fellows and make his own fortune. Possibly the gas companies might not appreciate his invention, but it would be open to them to buy it up and suppress it, at any rate, until the next clever man came forward.

* * *

Jan Szczezanik's Process of Colour Photography.

We published a short time ago an abbreviated paragraph, taken from a German photographic newspaper, in which a severe criticism of this process, from the pen of Dr. Neuhauss, was embodied. Our readers will remember the reply which the publication of the paragraph elicited from Mr. William Gamble. In the February number of the "Photographische Correspondenz" a letter appears, in which Jan Szczezanik himself characterises Dr. Neuhauss's attack as unjust. He writes that he has substituted stable for the unstable colours he previously used, and that fixed points, made with these, have been exposed to sunlight for weeks without fading. He also states that he has worked out a simple process for transparencies and constructed a camera for landscape work. As the process was worked out eight years ago and a patent granted for it in 1896, it is impossible that Lieutenant Slavik can have obtained a patent for a precisely similar process. So far as we can gather, there appear to be distinct features of novelty in the Szczezanik process. If the difficulty of fixing the colours has been overcome, there should now be some merit in it. The process differs from that of Dr. Neuhauss, because the colours are isolated, whereas in the latter they are mixed. The "Photographische Mitterlungen" draws attention to a patent taken out by Edward R. Hewitt in 1895, in the United States, which it affirms is identical with that of Lieutenant Slavik. Paper, glass, or celluloid is coated with several layers of pigmented gelatine sensitized with bichromate of potash. The light penetrates through the thinnest parts of the negative to the lowest layer, whilst the half-tones only permit of the upper layers being affected, and the densest parts absorb sufficient light to keep the films soluble, where the picture should be white. We may, however, point out that the use of a polychromatic carbon process is even much older still. It can be traced back at least to 1879, when it was recommended by Sawyer. At the time of the publication of the Sanger-Shepherd process it was also pointed out that the stained gelatine process was anticipated by Charles Cros, but the Szczezanik appears to be a bleaching process, differing from any of these.

* * *

Theatrical Scenery.

Persons quite ignorant of art matters but who have acquired from newspaper critiques and other sources the common shibboleth of art terms—there are many such youths about, mostly with long hair—have often been heard to deride scene-painting as something quite beneath serious notice by artists. It is a pity that some of these gentry were not present at the dinner given the other day to "painters for the theatre," which was presided over by Sir Lawrence Alma Tadema, who was supported by a number of R.A.s and prominent men in other professions. For they would have heard the just tribute paid to these clever knights of the brush and palette. A successful scene-painter has, in fact, to go through an apprenticeship quite as arduous as that necessary to the man who paints on smaller canvases. He must be a master of design and of drawing, of perspective and of colour, besides which he has to wear a pair of mental spectacles, so that he can gauge the effect of every dab of pigment as it would appear from the distant dress

le. It is quite a mistake to suppose that scene-painting here slap-dash work. It is, of course, on a large scale, there is often as much finish in it as there is in a very picture. Many well-known artists have passed their novitiate in the theatre painting-room, and have taken to smaller canvases later in life. David Roberts and Clarkson Stanfield are two names, which occur in this connection. It is always a matter for regret that theatrical painting should be of such an ephemeral character. The beautiful scene which has charmed our eyes is destined, at the end of the run of the play for which it was designed, to be worked over in order to bear their painting. The chairman said, the other night, that he had seen upon the stage most beautiful landscapes, architectural scenes, and flights of fancy, which, alas! he knew he would never see again. He could only hold them in his memory as he did the achievements of the actors themselves, the beauty of whose art they did so much to enhance. This was high praise from a painter of the kind of Sir Alma Tadema. But we have been asking: Need these beautiful pictures quite disappear in mortal ken? Cannot photography preserve a record of them? It is true that the ordinary reproduction of a scene at the theatre is a dire failure. The actors and actresses look like dolls, and the painted scenery has little resemblance to nature. But by aid of the three-colour process it should be possible to preserve faithful records of these beautiful pictures, which would not only be valued by the patrons of the theatre, but as accurate memoranda, to help in the reproduction of any particular play elsewhere. Now that electricity is in such common use at the theatres there should be no difficulty about effective lighting, and the production of a picture in colours under such conditions should not be a matter of great difficulty. We commend the suggestion to all whom it may concern.

* * *

Century Back. The excerpt from the "Liverpool Photographic Journal" (now the "British Journal of Photography") of 50 years ago, which we gave last week, is specially interesting, inasmuch as it contains a critique on the exhibits at the London Photographic Society's—now the Royal Photographic Society—Exhibition in 1854. It may be mentioned that, prior to the opening of this Exhibition to the public, it was visited by the late Majesty the Queen, accompanied by his Royal Highness Prince Albert, and both, before leaving, expressed extreme satisfaction at the wonderful advance that photography had recently made. Both Her Majesty and the Prince were patrons of the Society, and took a practical interest in photography at that time. It will be seen from the reprint that the show contained nearly one thousand exhibits; that is more than has been shown in any Exhibition of the Society of late years. Many of the exhibits prove that the art, at that early period when it was only fifteen years old, was not so backward as many modern writers seem to infer. For instance, some prints from steel plates etched by the bitumen process by Bisson, were shown, as were some others by the late Fox Talbot, etched with bichloride of platinum through a preparation of gum. A large calotype from a negative on iodised paper three feet six long was in the Exhibition, and was in perfect perspective. This picture was probably an enlargement from a smaller negative. The Rev. W. J. Kingsley showed some excellent photographs of microscopic objects taken by artificial light. Some photographs of the animals in the "Zoo" were shown by the Count de Montizon. These pictures, we are told, were on a much larger scale than those that have been attempted of late, and were by the collodion process, which was then comparatively in its

infancy, as it was only published in 1851. Photographs of the phenomena of polarised light on various crystals illustrating the difference produced on iodide of silver and on bromide of silver. At that time it will be seen that Burnham Beeches was receiving the attention of photographers, and their beauty was fully recognised. The foregoing notes serve to illustrate the state of photography fifty years ago, and how forward it was, although still so young, for the Daguerreotype process and the Calotype process were only published in 1839. It is noteworthy the number of persons of high degree that then took an interest in, and practised, photography at that early date. The late Queen and her Consort were patrons of the Society. Sir Charles Eastlake (then President of the Royal Academy) was the President of the Society, and Sir William Newton one of the Vice-Presidents. Amongst the exhibitors at this Exhibition we find the names as well as of Sir William Newton, the Ladies Neville, the Hon. H. Kerr, Viscount Vigier, Count de Montizon, and Sir T. M. Wilson. These were, of course, amateurs, but not of the "press the button type," as they, perforce, had to prepare everything for themselves, from the preparation of the paper, or plates, to the finishing of the print.

* * *

Post-mortem Photography. This is a gruesome subject, but it is one which the professional photographer has occasionally to busy himself with. He may be called upon at any time by the police to take the picture of some dead body which has been found under suspicious circumstances, and in many cases such photographs have been the means of leading to the identification of some poor relic of humanity. On the other hand, mistakes are not unknown, in which such a picture has been mistaken for the presentment of somebody still in the flesh, and the error has not been discovered until, like Enoch Arden, the supposed dead man has turned up again, and made things very unpleasant for everyone concerned. People who have been comfortably buried and sincerely mourned have no business to upset their relatives by such quixotic behaviour. At the Paris Morgue it has long been the custom to photograph the flotsam and jetsam of humanity which finds a last resting-place there, and the pictures, often of a repulsive nature, are exhibited outside the doors with as little compunction as that with which a professional portraitist hangs out his specimen cases. But according to M. Bertillon, the well-known French police expert, whose identification system was adopted in our own country until it was displaced by the perfected fingerprint method, these post-mortem pictures are unreliable—or, at least, they were unreliable until a better way of taking them was elaborated. M. Bertillon has apparently been recently interviewed, and a record of what he said is reproduced in one of last Saturday's evening papers under the sensational heading, "Corpses Made to Live." With such an attractive title the matter will have been widely read, possibly with the suspicion on the part of some that it concealed an advertisement of someone's pills. Our own impression of it is that either the interviewer must have totally misunderstood what the expert said, the wording has suffered under the hands of the translator, or that M. Bertillon had it in his mind to fool the newspaper scribe to the top of his bent. However, he is first made to say that an ordinary photograph of a corpse bears little resemblance to the person as he or she appeared during life. With that statement we can have no fault to find; it is a truism. But he goes on to say that he has invented a new system by which "in future, we shall be able to make a corpse to all intents and purposes live again for a few moments, and give us sufficient time to take its

photograph. We inject two or three drops of glycerine into the corpse's eyes. This results in the pupils opening. Then we rub a very little rouge on the lips, and take our photograph. In many cases relatives of the deceased who had not recognised the actual bodies at the Morgue, have by our pictures, been able to identify the dead." We have before had tall stories about various scientific achievements from Continental sources, but this last, supposing that we are wrong in our idea that M. Bertillon was chaffing his interviewer, really out Herods Herod. We may presume that the pupils of the eyes, except, perhaps, in cases of death by narcotic poisoning, would be naturally dilated by the relaxing of the muscles. But supposing they were not so, would cocaine or atropine cause them to open, as those drugs do during life? And if not, would such an inert liquid as glycerine have any effect? To a photographer, the notion of rouging the lips previous to taking a picture in order to make the result more lifelike, will be estimated at its true value. But the whole story is too absurd to merit serious consideration, and probably we shall learn in due time that the opinions attributed to M. Bertillon were either never uttered or have been so distorted in transit, that they are no longer recognisable.

ON MAKING SOLUTIONS.

II.

WHEN treating this subject a short time ago it may be remembered that we greatly objected to the use of so-called saturated solutions, such solutions being liable to be saturated in name only, owing to causes, some of which are specified. As our readers are aware, we have always been staunch upholders of the plan of exact measuring and weighing of the various substances used in photographic operations, a "pinch" of this, and a "little" of that, and so on, are fatal to certainty of results, and to that economy of time which systematic and regularly carried out measurement render easy and certain. Hence our remarks will be properly supplemented by some hints from our own and others mode of practice in this direction.

When the making of any particular solution is in hand, it is to be noted that much depends upon the qualities of the substance to be dissolved: some readily pass into solution in either hot or cold water, some slowly in cold, and more or less rapidly in boiling; some, and especially so with sodium salts, more rapidly in hot than boiling, and so forth. Much depends upon the size of the crystals; yet there is a difference even here if the ultimate degree of solubility be the same. For example, the comparatively large cubical crystals of iodide of potassium dissolve very quickly owing to the fact that each little cube is rather an aggregation of crystals than one solid whole. The question arises, if there are large crystals such as carbonate of soda, or the older type of hypo, what plan should be adopted. It is, as we said before, so very easy to dump the crystals in a bottle, fill up with water, give a shake, wait until to-morrow, and then call the mixture a "saturated solution." No, the plan is to fix on a strength, say, for sodium carbonate, of 20 per cent.—it will be found a good plan, and one that will lend itself to ready reckoning to have solutions of 5, 10, or 20 per cent. strength—and then to get the crystals dissolved at once. If the work is to be done with despatch, the large crystals of washing soda—should that be used—must be broken down. How? Well, a properly appointed dark-room ought to be provided with a mortar and pestle, though we admit this has been in our experience the exception rather than the rule, that, when we have seen them, they have too often been in what can only be termed a filthy condition—but, failing the presence of a clean mortar, the

crystals may be crushed by being packed very loosely in a piece of strong brown paper, the ends turned in, and the packet placed on the floor or a strong bench, and strongly battered with a hammer or other heavy object. They will then be ready to dissolve, and may be placed direct into the store bottle, and the required quantity of water poured on, then, if the bottle be frequently shaken the crystals may be dissolved in an hour or two! Far better is it to use a glass bottle; the solution will take place rapidly, an occasional stir being given; but this must be done in a separate vessel, not the glass store bottle, which might be instantly cracked by hot water. We will describe a very simple and efficient method we have seen for making a stock solution of carbonate and sulphate of soda, a Winchester quart only at a time. An old half-pound tobacco tin (the cylindrical shape) was pierced with a number of small holes in the bottom—made, we were told, by jabbing with a bradawl—and round this bottom was tied a double thickness of old muslin. A complete percolator was thus formed. Next an enamelled iron funnel was taken from its place against the wall and placed in the Winchester; the percolation containing the weighed quantities of contused soda crystals and sulphate of soda was placed in the funnel; boiling water was then poured on to the crystals (becoming cooled by the action) and, in about the time it has taken to write this, the crystals were all dissolved. Cold water was then added to the required bulk, the bottle well shaken and placed in its proper position. We noted one simple little expedient; the stopper, while the whole was cooling, was placed wrong way in, to prevent, we were told, it becoming tightly wedged by air pressure, as the contents contracted as they cooled. The percolator was well rinsed out, and hung up ready for use for the same or any other crystal solution. When larger quantities are to be dissolved, as, for example, in the case of hypo, this plan would not be so useful. We have seen a piece of cane bent into a circle, canvas slackly secured to it, and the whole hung inside the top of a huge jar, the hypo crystals being placed inside the canvas receptacle, and hot water poured on. When hypo solution is needed for immediate use, hot water should be used, as, in the act of dissolution, a large amount of heat is absorbed and the solution would be ice cold, even in summer time. Large users have all their own plans; we will merely mention one. The containing vat had two strong bars run into the sides about eighteen inches from the top. On these bars is placed a cwt. cask of hypo, bored through the bottom with a number of apertures made by a centre-bit, rough canvas being nailed over them. Upon the admission of water into the vat till it reached some little distance above the bottom of the cask, solution took place without attention being required, the only precaution necessary being to see that the whole was well stirred up to equalise the density, when the cask, emptied of its contents, the solution, was removed. Referring now to particular crystals, we may instance alum, which is very soluble in hot water, and only to the extent of about ten per cent. in cold. Bichloride of mercury is much more soluble in hot than cold, and the same with bichromate of potassium. These three chemicals can be bought at little or no increase of cost, ready powdered, and it is much better to obtain them so. A caution may be given about the heavy form of pyro; it is apt to go "lumpy" in parts, in which case solution of the lump is not very rapid; before placing the water these aggregations should be crushed, or there will be a tendency for them to remain at the bottom of the bottle unnoticed, and the solution then to be uneven in strength. Finally, we refer again to hypo, which can now be obtained in "pea" crystals, or very fine granulated crystals, either of which readily dissolve. We have not found it necessary to make a complete list of all the substances

ly to be used, but we have, we trust, given sufficient information to be really useful in practice and to throw the discredit upon the system or want of system of saturated solutions."

ON THINGS IN GENERAL.

Two letters respectively from Mr. W. H. Eady and Mr. G. Sims upon the subject so important to photographers—insurance—are very instructive, and fairly represent two sides of the question. In dealing with an insurance company one is met—in a modified degree, it is true, seeing that they are more subject to competition—with the same trouble that way companies provide for us when a claim for damages is made—the innocent have to suffer for the guilty. The various companies are so accustomed to fraudulent claims that they are very apt to look upon all as coming under the same category, and to look upon them with a little more than mere business carefulness. Few would conceive the extent to which the insurance companies are victimised or attempted to be, unless they have been behind the scenes a little. The consequence is any claim must rise very early to get the better of an insurance company. I know of a case when suspicion was aroused through books, invoices, and evidence generally of a photographic photographer, whose premises and stock had been burnt, being in perfect order, and who showed the invoice of a valuable article alleged to be consumed by the fire, leaving not a trace behind. In plain language, it was believed that knavery was at work, and the assessors actually had every particle of debris on the roof to basement passed through riddles, with the result that not a trace of glass or brass could be found. The claim, of course, resisted. With regard to the assessor's work, I cannot but believe that they work in the interest of the insurance companies. They are independent professional men; still, their income comes from the insurance companies. As an example of how they will act, I can quote an instance, the truth of which I can guarantee. There had been a small fire, and several garments were burnt, among them being one fresh from a tailor's that had not been taken out of the wrapping-paper. The assessor gravely asserted that the whole value, i.e., the retail price, could not be claimed for. It is not generally understood that in case of photographic policies the premium charged is often much less if the negatives are not included, and that is an argument in favour of a separate printing establishment.

Noticed in these columns a few weeks ago an extract from a post-card paper, under the head of "Post-card Stories." I give a better one. In a little monthly publication devoted to the interests of a bromide paper manufacturing company is an account of the mode of working and the daily output of a photographer in the country. Here is his account. He goes to work at six in the morning and goes on till noon. He prints his post-cards by daylight, one by one, in a printing press. He places a card in his frame (the negative being held for white margin), adjusts it truly, exposes, takes the print, drops it into the developer, fills in, exposes, and takes the second card; takes the first out of the developer, drops it into the hypo solution, and then puts No. 2 in the developer, etc., etc., No. 3, places No. 1 in water, out of the hypo, and so goes on in this sequence till noon. He has a boy to help him, but he is engaged in polishing the enamelled sheets being the cards on them as fast as they are ready. How many cards do my readers suppose are got through in these six hours working this way? We are told 300 is an

average, though, at a pinch, 500 or 600 have been done! Is there any reader with a spare glass-case to put this worker in? He is too good to live.

We have heard a great deal lately about residues; but though I hold no brief for the assayers I feel bound to say something for them. In the first place, as hypo residues were first in question, I have to say that either the collector of residues must have been exceedingly careless, and permitted a deal of rubbish to get mixed with his sulphide, or he sent it to a reducer who was a knave. There is no *media via*. I am fortunate in being able to quote from an assay report now before me of a well-known London refiner to whom was sent a small trial parcel of sulphide, collected after precipitation with liver of sulphur in the usual way. It is as follows:—Weight before melting, 11 oz. 80 grs.; after melting, 6 oz. 85 grs.; so that from this little parcel of sulphide more than half its weight in solid silver was recovered and paid for.

Here is the result of another batch containing mixed chlorides, sulphides, ashes of waste, untuned prints, and paper cuttings:—Weight, 21 lb. 4 oz.; product, 32 oz. 10 dwts.; price given for this 32 oz. of silver, 3s. 5d. per oz. This is a high price, but is accounted for by the fact that the sulphide was mainly from gold-toned prints. Otherwise the market price of silver would have governed the price, which would have been about 2s. or 2s. 3d. an ounce. These two assay reports I know to be genuine, and just as they arrived from the maker. After this, can any careful worker say it is not worth while saving sulphides. One point is worthy of note, and that is the relatively small amount of silver in proportion to the whole bulk of the latter parcel, and which adds to the cost of reducing—it only amounts to 12 or 13 per cent., and is probably attributable to the baryta of the P.O.P. or collo. paper used.

The extracts from the old pages of the Liverpool Photographic Journal are very interesting reading. One name strikes a chord of memory strongly. I am no longer in my teens myself, and my earliest recollections of photography are connected with the name of J. A. Forrest. Here in these "Fifty Years Ago" memories we read of Mr. J. A. Forrest being engaged with Mr. Edwards in photographing the moon, yet Mr. Forrest is still among us, and, last time I saw him, still a photographic enthusiast. Surely he must be the doyen of photographic amateurs. Yet, stay, in the very same set of memories we have a noted name which sheds lustre on this JOURNAL through its owner having occupied the editorial chair—Mr. (now Sir) W. Crookes. Still, I think Mr. Forrest could give him points in a mere matter of actual years.

Another subject of vast interest that is again brought under discussion is the metric system. Mr. Gotz, in his paper, "The Decimal and Metric Systems," gave an excellent resumé of the subject, and the arguments in favour of the adoption of the system, though I think his paper savours of the special pleader. Why, for instance, to show the cumbrousness of Roman numerals (now really a curiosity, and only used for very archaic or exceptional purposes) should he for 1849 write MDCCCXXXVIII? Why not for the last five figures put IX? Then, again, referring to the upholders of our British system, he says: "They are, in fact, missing the point entirely, for it is not a question of computing a perfect system of counting, but of bringing existing systems into harmony. This is begging the question. The question really is three-fold—to discover the best system for the daily use of the many; to

decide whether a practically perfect system for universal employment is found in the metric system; to decide whether these two considerations are to be entirely ignored, and whether it will not be to our best commercial interests to adopt the simple method now made use of by the majority of our customers abroad. The clumsiness of the metric system for general use—domestic use, if I may so put it—is proved by the fact that in everyday life the majority of the metric designations are entirely ignored, and, as I have before pointed out, a Frenchman would not ask for two hectogrammes and five decagrammes, nor even 250 grammes, of tobacco—he would say a quarter kilo. An Englishman, taking the same proportion of our unit—a pound—would say either a quarter pound or four ounces; if half this specified quantity were wished for we in England would want two ounces, against a metric man's hundred and twenty-five grammes, put at its shortest, and so on. The British system of weights and measures is complicated, but such of them as are used in everyday life lend themselves to ready calculation, and subdivided far more readily than does the metric system. But, as Artemus Ward's cabman said to him: "There's a deal to be said on both sides."

FREE LANCE.

PHOTO-RETROGRESSION, OR THE DISAPPEARANCE OF THE LATENT PHOTOGRAPHIC IMAGE.

[Read before the Fifth International Congress for Applied Chemistry in Berlin.]

ONE of the many practical advantages of the gelatine dry-plate over the older processes consists in the fact that development of the plate can be postponed to any convenient time after the exposure. Examples have been recorded where negatives were successfully developed a number of years after the plate had been exposed in the camera. On the other hand, the question has often been raised in how far results obtained thus are inferior to those which are produced on plates developed immediately after the exposure. Direct facts have been given indicating a gradual disappearance of the invisible photographic image. The study of this question requires more accurate methods than those ordinarily resorted to by the average photographer, and this may account for the reason why this question has brought out some quite contrary statements. The gradual disappearance of the latent photographic image seems to be a process exactly the reverse of the one which produces this image under the action of light. I would propose to designate this phenomenon under the name of photo-retrogression.

Very probably we have to deal here with what is called in chemistry a reversible reaction, similar to those occurring in all phenomena of dissociation and double decomposition, where, under the action of opposing energies which try to produce two different systems, a condition of equilibrium is reached. That such a condition of equilibrium may exist has been shown conclusively by the study of photo-decomposition of pure chloride of silver in sealed glass tubes, but an almost virgin field of study and research is still open for the physico-chemist who desires to determine the limits and factors of photo-dissociation of various chemical compounds. Such study should not be limited to silver salts, of which the susceptibility to the action of light is well known. Much more staple inorganic compounds may undergo profound changes, as I have been able to show when studying the photo-oxidation of hydrochloric acid.* This reaction is so much the more remarkable because by same hydrochloric acid in presence of oxygen oxidises under the influence of sunlight, whereas we know also that chlorine in watery solution evolves oxygen and forms hydrochloric acid. We are here in presence of a reversible reaction produced under

the influence of light and analogous to what occurs in photo-retrogression:—

I shall not try to decide here what chemical reaction occurs in the production of the latent silver image nor of its photo-retrogression. I consider any decisive opinion on this subject as idle talk as long as we cannot dispose of more thorough and complete laboratory investigations than the meagre work which has been published on this subject.

Without going into further general theoretical speculation we may state that photo-retrogression was known to exist long before the dry-plate was invented. In the daguerreotype process the image can only be retained in proper developable state during a few hours. For the wet collodion process a similar fact is known, although it might be ascribed here to the physical condition of the sensitive layer, which requires a certain degree of moisture. Photo-retrogression in gelatine dry-plates can be observed in such cases where the time of exposure has been limited to the very minimum, as, for instance, in undeveloped negatives. Even then it may be difficult to observe same unless under some particular conditions. In all cases where more than enough exposure has been given, photo-retrogression becomes much less apparent, and this is, perhaps, the reason why so many contradictory statements have been made on this subject. I have studied photo-retrogression on dry-plate films, bromide papers, and chloride papers. For all my experiments I take a standard negative purposely selected so as to show delicate graduation with no high lights and no transparent parts. I also use a sensitometer scale, similar to what is used for ordinary sensitometer tests, and consisting mainly of a glass plate divided into numbered squares made up of different thicknesses of opaque pigment. As a source of light I use a normal candle, the same quality of candle being used in all my experiments. In order to minimise the errors of observation, the experiments have always been repeated at least four times. My way of proceeding consists in placing the strip of dry-plate, film, or paper in direct contact with the negative or sensitometer scale, and then expose same during a given time at a constant distance from the candle-light. All ordinary precautions are taken so that the experiment should not take place when the flame of the candle burns under normal conditions. In each series of experiments some of the dry-plates, films, or papers are developed immediately, the development being carried as far as possible, i.e., until the image does not gain any further strength. The results thus obtained are numbered and stored away for future comparison. An equal number of the dry-plates, films, or papers exposed under the same conditions are stored away in the dark undeveloped but are treated with the same developer afterwards at specified intervals. Proper precautions are taken while storing tests so as to exclude the possibility of outside influences on any of the light sensitive material. When developing any of these tests a developer of strictly the same composition and same temperature is taken, and development is carried on under exactly the same conditions, but in each case development is carried on as long as the image gains in strength or disappears regardless of beginning "fog." In each case I selected a developer which experience had indicated to be best adapted for each sensitive material. Some of the experiments were repeated using different developers, but in each case the results were only compared with those obtained by identical developers. I have observed, however, that whenever photo-retrogression was apparent same would be shown by each one of the developers, so that the nature of the developers seems to play no rôle in this phenomenon. In the first experiments thus conducted I came soon to the conclusion that certain varieties of films and bromide papers, also some chloride papers, show photo-retrogression to a considerable extent, even after relatively

* Backeland Bull. Acad., Royale de Bel. 1886, IX., No. 3.

port intervals, while other varieties, and especially dry-plates, do not show it so much. This is mainly due to some chemical differences in the emulsion, as will be explained further. In some varieties of bromide paper and films photo-retrogression is quite apparent even after so short a time as forty-eight hours. The image developed after this time was invariably weaker than the one obtained directly after exposure. At the end of a few days the results became much more decisive, and after two months, in some cases, only a faint image was all that the developers could bring out. Let me repeat here and insist on what I have stated before, that these results become apparent only in such cases where exposure has been insufficient, and where, consequently, the prints have been underdeveloped. In such cases only development can be carried on to full limits, and after all the silver salts, which have undergone the action of light, have been reduced, the image will not gain any further strength, even if the developer is left in contact for a considerable time. The only effect which such prolonged development may then produce is a general grey "fog" which covers the whole image without strengthening same or changing the relative density of the different parts of the first developed image. In full-timed prints—and by these we designate such ones as have practically received a slight excess exposure—this condition of affairs does not exist; by developing same we reach a phase where development has stopped, not on account of fear of "fog," but because the shadows and half-tones will acquire too great a density, which would prove objectionable in a negative, and which, in our experiments, renders it impossible to distinguish slight differences in the results. All experienced photographers will rather err too much than too little exposure to their negatives. This practice is very commendable in view of the fact that thereby the effect of photo-retrogression is avoided. However, there are many cases where full-timed exposures are not possible—example, in instantaneous work, and there photo-retrogression may have serious drawbacks. It may become more objectionable still in some methods of automatic printing and developing which are carried out nowadays on a large scale in some industrial establishments. As the amount of material involved in one of these operations may represent thousands of dollars at a time, it is quite natural that in such cases photo-retrogression deserves special attention.

A few years ago, when automatic printing and development, "photography by the mile," was first carried on in New York, it was brought to my notice that a large roll of bromide paper, about 500 metres long and 65 cm. wide, which had been developed automatically by artificial light, could not be developed to the proper strength, although the test strip, which had been developed under identical conditions, but developed immediately afterwards, had given excellent results one week before. The working device of the automatic printer, the steady quality of the print, the uniformity of sensitiveness over the full length of the paper, and the conditions of the developer, were all critically examined. At that time I had just started my investigation of the photo-retrogression, and I was able to trace to this phenomenon the difference in results. That this was really the case of all the trouble was proven beyond doubt by some direct experiments which were made afterwards. Mr. A. E. Munstone, of New York, reported to me similar cases which had been observed lately during the development of strips of negative and positive films, same as are used nowadays for animated photographic exhibitions. For instance, a large roll of films exposed in Europe, and of which a test strip had been developed there so as to make sure that the exposure was correct, was shipped to New York for further development. On arrival there it was found that the pictures developed too weak, so as to make the results unsatisfactory. The same developer was used as in Europe, and great stress was put on the quality of the chemicals, but without avail. Finally, the undeveloped

portion of the film was reshipped to Europe to the party who had developed the trial strip, but he could not obtain any better results. Another case was cited to me of an undeveloped film which was sent to New York from the Philippine Islands. This film had also been exposed in an apparatus for animated photographs, and by a very competent operator, who tested a portion of the strip for exposure and development. On arrival in New York the image could not be developed; and showed all signs of photo-retrogression. In this particular instance the film had been submitted for a relatively long time to a humid and warm climate, which includes conditions which are most favourable for producing photo-retrogression, as we will see further.

I have tried by direct experiment to determine what factors have an influence on photo-retrogression:—

Temperature.—Dry-plates, films, bromide paper, and chloride paper were exposed as indicated above. A certain number of the tests were developed immediately; a same number of them were enclosed in a bottle provided with a glass stopper and kept in a refrigerator at a temperature ranging from one degree C. to four degrees C. An equal number of tests were kept during one week in a stoppered glass bottle in a box, of which the temperature was kept at 40 degrees C. to 48 degrees C. At the end of three days photo-retrogression was very apparent, for the tests kept at a high temperature, whereas it was not noticeable even after two weeks for the tests which had been stored in the refrigerator.

Humidity.—Same tests as above were repeated. Some were placed in a large earthenware jar provided with a tight cover. In the centre of the bottom of the jar was placed a large cylindric glass containing sulphuric acid 66 degrees B., so as to keep a very dry atmosphere. Other tests were placed in a similar jar, but the glass of same, instead of sulphuric acid, contained cotton soaked with distilled water, so as to saturate with humidity the air of the jar. The two jars were left in a room of which the temperature oscillated between 18 degrees C. and 27 degrees C. At the end of two weeks the tests of both jars were developed. All showed photo-retrogression, but the tests in the humid jar showed same much more than the ones contained in the dry atmosphere.

Chrome Alum.—In all above experiments I had the opportunity to observe that some dry-plates which I used showed less photo-retrogression than some films, bromide papers, and chloride papers. Then, again, films and bromide and chloride papers of different makes showed results quite different with each brand. I soon found out that those papers which were most subject to photo-retrogression had either a slight acid reaction or contained noticeable amounts of chrome salts. In order to determine in how far the presence of chrome salts has an influence on this phenomenon, I made a bromide emulsion, and, after dividing same in two portions, I added to one of these about one per cent. chrome alum of the amount of gelatine used in the emulsion. The other portion received no addition, and both emulsions were used to coat some test plates and papers. The tests were dried under the same conditions, and afterwards exposed and developed at long intervals. Photo-retrogression was much more apparent with the tests containing chrome alum than with those without this salt.

Acidity.—In the previous experiment I noticed that the test which contained chrome alum showed a slight acid reaction on litmus paper. In order to determine whether acidity or chrome alum has the greater influence on photo-retrogression, I repeated the experiment in the following way:—To the whole of the emulsion I added the same amount of chrome alum. Then I divided the liquid into two portions. One of the portions was used to coat test plates just as it was; the other received an addition of some drops of diluted ammonia, just enough to produce a very slight alkaline reaction. An initial test showed little or no difference in the sensitiveness

of both emulsions, but after a few weeks photo-retrogression was less apparent in the tests which were coated with the slightly alkaline reaction. I next compared a neutral emulsion containing chrome alum with the same emulsion containing no chrome alum, but enough citric acid so as to give it a distinct acid reaction. The acid emulsion without chrome alum produced more photo-retrogression than the neutral emulsion with chrome alum. In all these experiments the tests were carried on in the same way and kept under the same conditions for each set of experiments, but in certain cases development of all the tests of each set had to be postponed for a more or less longer period until such time was reached, when the difference in the results was sufficiently apparent to enable me to draw conclusions. These experiments explain why certain brands of dry-plates, films, or papers show more photo-retrogression than others. This phenomenon must undoubtedly be attributed to chemical action, and the chemical conditions of the different emulsions determine the speed and intensity with which it occurs. It is a known fact that emulsions which are intended for films or paper receive almost always an abundant addition of chrome alum, so as to render the gelatine coating less soluble, and to produce at the same time a more viscous liquid which is better adapted for certain coating machines. Dry-plates, on the other hand, require no such addition of chrome alum. Furthermore, if emulsions are made by the "boiling" process where the "ripening" is obtained by a prolonged application of heat, their final reaction will be neutral or very slightly acid, and the smallest amount of chrome alum may give them a distinct acid reaction. Emulsion "ripened" with the ammonial process will almost always be slightly alkaline, even after long washing, and the addition of a small amount chrome alum will not necessarily give them an acid reaction. I should mention here that emulsions made with the ammonia process, but separated by a centrifugal machine, may produce, after reincorporation of the silver bromide with fresh gelatine, a neutral or slightly acid reaction, which may become more apparent after the addition of chrome alum. Let me also call attention to the fact that these slightly acid or neutral emulsions give generally papers or dry-plates which have better keeping qualities and which are less liable to become "foggy" with age. It so happens that such emulsions are also those which are most liable to show photo-retrogression. In above statements, whenever I referred to chloride papers, I meant papers of the "velox class," coated with such emulsion which contain chloride of silver in the gelatine, but without any excess of nitrate of silver or any other soluble silver salt, and which are intended to produce images by alkaline development, and not by printing-out methods.

The facts mentioned here add new strength to the supposition that the latent photographic image is due to a chemical and not to physical condition. Many hypotheses, none of which has been sufficiently demonstrated, have been proposed to explain this subtle chemical reaction. Whether we try to explain the latent photographic image by the formation of free silver, sub-bromide and sub-chloride of silver, or, again, by the existence of oxy-sub-bromides or oxy-sub-chlorides, above-mentioned facts point out that photo-retrogression occurs by chemical action. This action is probably the reverse of what occurs in the formation of the latent image. Whether in this phenomenon oxygen directly or indirectly plays a rôle we cannot say yet, and further work in this direction may give us a better insight in this matter; but I would call your attention to the fact that a neutral or alkaline light sensitive layer would be in better condition for absorbing free bromide or chlorine or oxygenated derivatives of same than if same had an acid reaction. As far as regards the influence of heat and moisture, same is sufficiently accepted as being of great importance in all chemical reactions; in this particular case we are not astonished to see

again these two factors as being of very marked influence in photo-retrogression.

Conclusions.—Photo-retrogression, or slow disappearance of the latent photographic image, takes place in glass plates, films, and paper, coated with gelatine silver bromide or gelatine silver chloride. Photo-retrogression is especially apparent in under-timed images, and much less noticeable in over-timed images. Photo-retrogression may, under special conditions, become apparent in dry-plates, films, or paper forty-eight hours after exposure, and may increase until the latent image has nearly disappeared. Photo-retrogression occurs quicker at high than at low temperatures. Photo-retrogression occurs quicker in a humid than in a dry atmosphere. Photo-retrogression is less apparent in neutral or slightly alkaline sensitive layers than in such ones which have an acid reaction..

DR. LEO BAEKELAND.

"LAISSEZ FAIRE."

[A Paper read before the Professional Photographers' Association.]

WHEN our president requested a paper for this evening's discussion it occurred to me that the subject most à propos at this dreary time of the year—the topic most likely to be of general interest—would include "Causes of Business Depression."

Probably, only very carefully managed studios have passed the test of recent annual audits at all brilliantly, and the outlook in these days of fresh war disturbance and changing trade conditions does not appear particularly rosy for the general body of photographers. Of course nothing is simpler than to ascribe bad times in the studio to bad business all round, or to suggest that the swing of the commercial pendulum will once again bring round golden years to our special calling.

But many things point to an unsettled condition in photographic business—which is likely to become more marked in the future—and the question arises whether this is due to any causes over which the P.P.A. may exercise beneficent control. It is generally admitted that, while the average quality of professional portraiture is higher to-day than it ever has been, the difficulty of securing sufficiently large "turnovers," to make it pay, is greater now than in bygone years. Photographers of the "good old days" lament the introduction of dry plates, and ascribe lessened prosperity to the enormous increase of photographic establishments which followed the simplification of technical operations.

Others believe the widespread practice of giving invitation sitting has produced a slump in photographic interest, from which a speedy recovery can hardly be expected; while again anathemas are lavished upon post-card publishers by those who think they see in this craze a break up of remunerative publishing work.

But, important as these factors may seem in considering causes of photographic depression, there are others which have encountered far too little opposition relative to the mischief they create. I allude to the cheap "newspaper" enlargement, the "free" portrait, the meat or soap, or tobacco advertising schemes.

Within recent years a thoroughly mean and attenuating system of despoiling photographers of their business has grown up by which men of no artistic ability (but skilful in assimilating to themselves the fruits of other men's labours) have caused injury to the regular established photographer.

One may rarely pick up a newspaper without alighting upon meagre and audacious announcements, intended to gull the public into the belief that it will get something photographic "free," or making the impudent and offensive insinuation that the "life-sized" enlarged portrait that the advertisers sell for five or six shillings is similar to the "two guinea" work of the professional photographer. Moreover, the use of such adjectives as "magnificent," "artistic," "beautifully finished," and the assertion that these qualities are found for so small an amount must eventually produce the impression that a photographic enlargement is a synonym for cheapness and vulgar pretension. It is seldom of use appealing to newspaper proprietors, for some of the worst advertisements are actually put forth as photographic enterprise, in which they are themselves directly interested.

Shall we then remain content with an attitude of *laissez-faire*? Are we to allow this wholesale depredation to go on unchecked, to

ote our portraiture being vulgarised in enlargement, and often framed in execrable taste without attempting to limit the operations of these people, who not only use our work, but deliberately try to misrepresent us in the eyes of the public? Many of us are accustomed to hear clients (who can well afford artistic work) apologising for possessing these wretched things on the score that "they cost so little." While this may be true enough, will anyone suppose that these crude enlargements can hang in thousands all over the country without degrading the popular taste and interest in bromide, or indeed any productions on a large scale.

Photographers who imagine they suffer little or no curtailment of business on this account forget that the profitable use of their own negatives must be minimised, otherwise the expensive and persistent advertising could not be made to pay.

I suggest that this diversion—this unfair diversion—of business is a source of weakness to us, and also seriously threatens the prosperity of that large number of artists who are dependent for commissions or daily employment upon the regular photographic establishment.

It is often easier to diagnose a malady than to provide a remedy, but those gentlemen who have considerable capital and interest at stake in portrait studios throughout the country can be sufficiently impressed with the necessity of keeping photographic business to photographers where they may be found ways of dealing with this trouble needing no heroic measures.

The action we may take cannot gain anything by appeals to public sympathy, but should rest upon the commonsense basis of giving the best value for money. It is the only argument that eventually wins, and is the only one we need expect the public to consider in the present hunt for bargains.

But is anything easier to demonstrate than this—that if a man will only spend five shillings on an enlargement he will get better value from the photographer who took the negative than from a man who tries to reproduce a paper print, with its attendant coarseness, and lack of detail. I think this might be made the keynote of our opposition, and to drive it home every professional might possess an example (made from a paper print by one of the newspaper firms) and use it for purposes of comparison with his own work. Photographers will know well enough how to make this comparison effective in using their own negatives.

An ounce of practice is worth a ton of theory, and I can assure our members that this simple plan will bring many guineas to them which they might otherwise miss. The exhibition of "an awful example" does more to clinch an order for a well finished portrait than any amount of persuasive talk. Within the past few months I have had opportunities of examining a great many of these so-called "crayon" enlargements; the draughtsmanship is thoroughly childlike, and the delicacy with which the powder is rubbed into the enlargement renders one forcibly of the genius of the pavement.

The public are amiably reminded that "the better the photograph the better the enlargement will be"; also that "the crayon and Indian ink used in the production of the portraits cannot fade," the latter statement being as correct as the former; any hope of the likeness improving by keeping is quite destroyed.

It is not often a newspaper has the courage to exhibit the photographic article it advertises, but this week, in Hull, there are to be seen in the office windows of a much circulated local print, some very fine specimens, labelled, as usual, "Two guinea portraits for 6d." One of these specimens has been purchased, and is in the hands of your inspection. This public exhibition seems, at all events, more honourable proceeding, and, from the professional photographers' standpoint, a few hundred objects of this sort shown about the country would be most gratifying. Unfortunately, the absurdity of expecting a two guinea portrait for 6s. 6d. is not always made plain by such striking proof, the victim generally parts with his money without the awakening. Therefore, we must either discredit this advertisement, or, by doing nothing, risk the public accepting the elements as truth. So far, I fear the policy of photographers has been summed up in the words, *laissez-faire*. Is the old habit to come a motto of our profession, in this, as in other business evils? We have heard photographers suggest that the P.P.A. might become the centre from which information should be disseminated for the caution and guidance of its members, as these schemes crop up.

With regard to "free" enlargements, short articles, describing the manner in which these things are worked, might be printed by our

association and circulated by the members with their ordinary business "literature." And there can be no insuperable difficulty in communicating to the weekly Press notes on this matter, after the style of the "Truth" exposures. When "free" enlargements are advertised to assist the sale of some trade article, such as soap or meat extract, the example of the P.P.A. resistance to the Liebig Company in Hull may be worthy of imitation.

Readers of the BRITISH JOURNAL OF PHOTOGRAPHY know how that short campaign produced a vigorous protest against the "Oxo" advertisements on the part of the Hull Grocers' Association, and ended in the rapid disappearance of photographic enlargements from the Hull grocers' windows. It is true the Liebig Company still advertise, "Insist on having a 'free' photo enlargement coupon with every bottle you buy," but the number of housekeepers who will consume eighty bottles of "Oxo" and trouble themselves to save the coupons need not be a source of worry to us. If there is a moral deducible from this experience it is that a thing worth fighting for at all requires prompt action and professional unity, and then difficulties like this lose their importance.

In conclusion, may I suggest to my confrères the possibility of ultimate good accruing to us if the present quietness of business and external competition for photographic works brings about a more interested attitude and desire for co-operation. While there may be photographers in every town who in bad times try to fill up their leisure in devising price-cutting methods of business that lead to self-extinction our association may find it the psychological moment for attracting to itself the best services of its members and extending the sphere of its usefulness.

T. C. TURNER.

WHY NOT ILLUSTRATE BOOKS WITH STEREOSCOPIC VIEWS?

[From The Publisher's Circular.]

SIR,—I am neither publisher nor bookseller, but as one generally interested in literature it appears to me that book illustrations might be made much more interesting and explanatory if the stereoscopic principle were adopted. The fact that this requires two pictures side by side would not increase the cost of the process block, as the surface would be no larger superficially than a whole page illustration. Of course, this principle would not be available where the author only supplied wash or outline drawings to the block maker; but where photographs of solid objects, scenery, figure groups, architectural work, etc., have to be copied it would only be necessary to take two views with a binocular hand camera, or with an ordinary camera by the well-known plan recommended by Prof. Flinders Petrie in his last work on archaeology. Nowadays nearly every one is provided with a hand stereoscope, but even if such were not the case it would be very easy for the binder to make a receptacle in the cover of the book to hold a thin piece of wood on which the necessary lenses could be mounted. The whole of this would involve but a very trifling cost; indeed, the opticians would soon meet the requirements of the reading public by providing a cheap form of instrument adapted for book use. I have one by me which was issued with the early numbers of the "Stereoscopic Magazine" many years ago, but indeed after one year book buyers would not require the instrument to be provided with the book—it would be quite as common as a paper-knife. The effect gained by this method of illustration would be most advantageous when the plates were accompanied by descriptive letterpress.—Yours obediently,

C. J. TABOR.

The Press Club, Fleet Street, E.C.

February 9th, 1904.

[Mr. Tabor's suggestion is certainly interesting, and as many stereoscopic views are already printed from half-tone blocks we see no reason why it should not be carried out. Stereoscopic lenses and holders are so cheap now as to be found in every house. Illustrated guide-books would be much more interesting if the views were stereoscopic.—Ed. "P. C."]

THE Prince and Princess of Wales visited the new offices of the "Graphic," in Tallis Street, Victoria Embankment, on Thursday afternoon, and on that occasion set the entire machinery in motion by means of an electrical lever.

AMERICAN PHOTOGRAPHY AT THE ST. LOUIS EXPOSITION.

[From *Wilson's Photographic Magazine*.]

THE following letter speaks for itself, and should be carefully read by those who desire to exhibit their photographic work at the St. Louis Exposition.

The invitation mentioned in the letter as having failed to bring response was read at the last national convention, but the Association failed to appoint a committee to take charge of the matter. Mr. J. George Nussbaumer, of Buffalo, was appointed juror to serve on the Committee of Selection, and there the matter apparently ended. It is regrettable, indeed, that this neglect has placed American photography at a serious disadvantage as far as adequate representation at the World's Fair is concerned.—En. "W. P. M."

St. Louis, January 15th, 1904.

To the Editor: "Wilson's Photographic Magazine," New York.

DEAR SIR,—Under date of July 29th, 1903, invitations were extended by this department to seven photographic societies to name one member each of a proposed Committee of Review and Selection. The duties contemplated for this committee were to examine and grade photographs offered for exhibition. Inasmuch as the majority of the societies have failed to respond to the invitation extended to them, it becomes necessary to change the programme, and new regulations have been formulated, a copy of which is enclosed herewith.

I will be pleased to have you give publicity to these regulations in the interests of the photographic fraternity.—Very truly yours,

JOHN A. OCKERSON,

Chief, Department of Liberal Arts.

Regulations governing the admission of photographs as exhibits in Universal Exposition to be held at St. Louis, April 30th to December 1st, 1904.

That portion of circular dated July 29th, 1903 (page 342, August 1903, of this Magazine), relating to the admission of photographs is hereby rescinded.

The following information is submitted for the guidance of photographers who contemplate entering photographs as exhibits in the Universal Exposition, which opens in St. Louis April 30th, 1904.

First.—Application for exhibit space should be made without delay of forms or blanks furnished by this office. Full information should be given as to number, character, and size of pictures to be submitted, together with a sketch showing proposed arrangement on walls, folding screens, or in albums.

Second.—All pictures offered must be mounted, matted, and suitably framed or otherwise properly prepared for ready installation in the space devoted to photographs, the owner assuming all risk and expense of shipments to and from the Exposition, as well as the installation and care of same while on exhibition.

Third.—All photographs accepted as exhibits will be subject to review by an International Jury of Awards, composed of members from each of the several countries making photographic displays.

Fourth.—All photographs should be shipped so as to reach the Exposition not later than April 1st, 1904. Shipping labels will be sent to accepted exhibitors on application to this department.

The railways have granted free return of goods on payment of full rate to the Exposition, provided shipments are made in accordance with adopted regulations.

Fifth.—Freight and express charges and all charges appertaining to the transportation of photographs must be fully prepaid at the point of shipment, and the goods delivered at the Liberal Arts Palace clear of all charges of every description incident to transportation.

Sixth.—Photographs offered as exhibits must be the individual work of the exhibitor named in formal application for space.

Seventh.—There is no charge for exhibit space, and suitable screen walls will be constructed in the Liberal Arts Palace on which photographs may be hung.

Eighth.—Special adornment of space or extra lighting will be at the expense of the respective exhibitors requiring same.

Ninth.—General rules governing exhibits, their installation, the system of awards, shipping regulations, etc., will be furnished on application to this department.

JOHN A. OCKERSON,

Chief, Department of Liberal Arts.

Exhibitions.

THE SCOTTISH PHOTOGRAPHIC FEDERATION ANNUAL MEETING.

THE first annual general meeting of the Scottish Photographic Federation was held in the Sandeman Library, Perth, on Saturday, Mr. Henry Coates presiding. There were 29 delegates present, besides a number of associates.

The secretary's report showed that the federation was formed on January 17th, 1903, when sixteen societies federated. At the present date the federation was composed of twenty-four societies, working for the betterment of Scottish photography. The list of lecturers, demonstrators, circulating lectures, and lantern slides, as well as the list of judges, although published after many of the societies had made their arrangements for the session, were well taken advantage of, no fewer than fifty calls having been made on these facilities. The exhibition—the Scottish National Salon—was a distinct innovation in Scottish photography, and as to its success it was needless for him to speak, at least there. Exhibition promoting societies had included in their prospectuses special classes for associates of the federation.

The lantern slide competition had been a great success, no fewer than 268 slides being entered for competition. The awards of the judges Messrs. Godfrey Bingley, Ezra Clough, and Alex. Keighley—were as follows:—Societies competition (18 slides in a set), for beautiful solid silver challenge plaque, presented by the president: 1, Glasgow Eastern Amateur Photographic Association; 2, Dundee and East of Scotland Photographic Association; 3, Paisley Philosophical Institute (photographic section); 4, Blairgowrie and District Photographic Association. Associates' competition (3 slides in a set), for prizes presented by three members of Council—Messrs. Eadie, Macdougall, and Stewart: 1, W. S. Crockett, Glasgow Eastern; 2 and 3, Arch. Campbell, Dundee and East of Scotland; 4, John B. MacLachlan, Blairgowrie and District. As the rules precluded anyone taking more than one prize, third prize went to Mr. MacLachlan. The judges also selected three single slides for special mention—viz., "Women in Field," by No. 10 Paisley; "Kilchurn Castle," by Arch. Campbell; and "The Last Rose of Summer," by James Donaldson, Blairgowrie and District.

The treasurer's report showed an income of £26 1s. 4d., and an expenditure of £8 4s. 3d., leaving a balance in favour of the federation of £17 17s. 1d.

Both reports were unanimously approved.

Office bearers for the season were elected as follows:—President, Henry Coates (Perthshire Society of Natural Science); vice-presidents, David Horn (Glasgow Southern) and G. D. Macdougall (Dundee and East of Scotland); treasurer, Archibald Campbell ("Dundee Advertiser"); secretary, John B. MacLachlan (Blairgowrie and District); Blairgowrie; council, J. W. Eadie (Monklands), R. Milne (Paisley), W. A. Frame (Glasgow Southern), S. Stewart (Kirkcaldy), V. C. Bain (Dundee and East of Scotland), A. Symons (Wishaw and District), John M. Dunn (Brechin), John J. Munro (Stirling and District); auditors, Messrs. Murdoch, C. A. and R. C. Thomson.

It was decided that the next annual meeting be held in Glasgow, on February 11th, 1905, and that the annual exhibition also be held in Glasgow in 1905, to open on the day of the annual meeting.

It was decided that the federation arrange an excursion for associates to Callendar on June 11th, it being remitted to the council to arrange details.

It was agreed, on the motion of Mr. Dunn, Brechin, that a federation portfolio be started, and the matter was remitted to the council for arrangement.

It was agreed that the federation publish a year book, and it was remitted to the council to see this done.

Mr. Frame drew attention to the need of a photographic periodical in Scotland, and thought the federation might take up the matter. After discussion it was remitted to the council to formulate a scheme for the consideration of the societies.

Hearty thanks were accorded the judges, who had kindly acted during the session for the federated societies, and also to the judges who had performed the arduous duty of judging the lantern slide competition.

Mr. Mackenzie, exhibition secretary, reported that he thought the result would result in a small balance in favour of the federation. At the council meeting, held immediately afterwards, it was decided that the lantern slides mentioned by the judges be formed into a set for circulation amongst the societies. It was remitted to the secretary and treasurer to get ahead with the publication of the Year Book, and put into it as much information as possible. Messrs. G. H. Depledge, Paired, and the president were appointed an excursion committee. The secretary was instructed to ask the judges who acted last year to continue their services, and several other names were mentioned for addition to the list. It was agreed that the next council meeting be held at Perth on March 26th.

FORTHCOMING EXHIBITIONS.

February 27 to March 5.—Birmingham Photographic Society. Patrons of L. Lloyd Hollies, Church Road, Moseley, Birmingham.
February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Essex.

March 5. Last day for entries February 18.—South London Photographic Society. Entry forms from W. Calder Marshall, F.C.A., Glenton Road, Lee, S.E.

March 5-12.—Brechtin Photographic Association. Hon. Secretary, Kirk, 1, Infirmary Street, Brechtin.

March 8-9.—G.E.R. Mechanics' Institution (photographic section). Secretary, A. Woolford, 16, Grove Green Road, Leytonstone.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Clark, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 22 to April 5.—Glasgow Southern Photographic Association. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, J. King, Hurst Bank, Selsdon Road, Sanderstead.

Patent News.

The following applications for patents were made between February 1 and February 6, 1904:—

Printing.—No. 2,505. "Improved means and apparatus for photographic printing." (Date applied for under Patents Act 1901, 1st August, 1903, being date of application in Switzerland). Complete specification. Nelson King Cherrill.

Amateur Photography.—No. 2,506. "Improvements in and in connection with amateur photography." Nelson King Cherrill.

Camera Holder.—No. 2,568. "Camera holder and clamp. Complete specification. Hermann Conrads.

Photography.—No. 2,693. "Improvements in or relating to photography." James Hewitt and Ezra Barnwell Miles.

Developing Machines.—No. 2,998. "Improvements in or relating to photographic developing machines." (Date applied for under Patents Act 1901, 9th February, 1903, being date of application in United States). Complete specification. Burton James Holcombe.

SWEET are the Uses of Photography."—At the Derby Police-court the other day a man named Matthew McLeavy was charged with having been drunk and incapable in Brook Street, Derby, early on the morning last. This was his twenty-third appearance, and on the last he was placed upon the "Black List." Defendant: "It was very degrading for me, I can assure you, having my name up in all the pubs, and it makes me feel vexed." Fined 10s. costs.

New Apparatus, &c.

Barnet Extra Rapid Plates. Manufactured and sold by Messrs. Elliott and Sons, Ltd., Barnet.

The high reputation the Barnet plates have won for themselves in the esteem of a large number of photographers will doubtless be confirmed by the issue, which has recently been made, of a "specially fast" extra rapid series. We have tried a sample box of these plates, and find the claim for speed well established. The subject was the front elevation of a house in this smoke-begrimed metropolis. The sun justified its existence by a vain attempt to beguile us with the idea that spring was approaching, and we closed the diaphragm of the lens to f/64 and gave a hand exposure, which we should estimate as of barely a second's duration. The plate developed normally with pyro-potash, and did not exhibit any trace of fog. The character of the negative reminded us forcibly of our previous experience with Barnet plates. The shadows are clear, the gradations delicate, and the grain is remarkably fine. The emulsion, in fact, combines those characteristics which the photographer seeks in a plate for the studio, and, considering the rapidity Messrs. Elliott and Sons have succeeded in giving to it, we have no doubt professional photographers will appreciate this "specially fast" series.

THE Camera Club.—The honorary secretary regrets extremely the late appearance of the "Journal" this month. When last month he congratulated himself and the members upon the fact that he had been able to announce four lectures in advance for February, he was sanguine enough to hope this happy state of affairs would continue. Unfortunately, it has not done so; and, owing to lecturers who have promised, but, alas! have cried off at the last moment, he had been unable to arrange the fixtures for this month until now. In his opinion—and he believes that of most members of the club—the principal use of the "Journal," without in any way depreciating the valuable reports of lectures recorded therein, is to give notice to members of forthcoming events, more especially as we have no other means by which members can be notified of arrangements made by the hon. secretary for their entertainment and instruction. His endeavour always is to announce the lectures as long before as possible. But, unfortunately, "there's many a slip 'twixt cup and lip," and his arrangements sometimes fail. Under these circumstances, he feels sure that he can rely on the sympathy of all the members. Last October the Kotaibis, a tribe whose country lies east of the communication between Aden and Dthala, revolted, and attacked the fort of Sulek, occupied by a party of sixty men of the 102nd Grenadiers, under Captain Lloyd-Jones. For four days the small garrison was practically besieged, and then were relieved by a force which enabled a counter attack to be made upon the enemy. Unfortunately, in a gallant charge made on the part of the 123rd Rifles, Captain Lloyd-Jones, who was with them, received no less than five wounds, which placed him *hors de combat*. His condition was at first critical, and amputation was, at the least, anticipated; but the most recent news is that such serious consequences have been avoided, and that he is doing so well, that he will shortly be able to return to England. He has the sincere sympathy of his fellow members, who trust that the sea voyage will, as is so often the case, effect wonders, and who wish him a speedy recovery from the severe wounds from which he has been so long suffering. It has been noticed that of late smoking concerts have not been so popular in the club as heretofore. When, however, we can look forward to one for which the arrangements are being kindly made by a member of such vast experience in the dramatic world as Mr. Guy Waller, we may be sure of having an excellent programme and a full audience. Members are reminded that a club supper will be served after the concert. The name of Mr. E. W. Maunders, F.R.A.S., Superintendent, Solar Department, Greenwich Observatory, is so well and widely known, that it is only necessary to draw attention to the fact that he will lecture to us on such an interesting subject as "Mars and its Canals," on Thursday, the 18th. Professor Louis has travelled extensively to many corners of the earth as consulting mining engineer; Mr. Percy Macquoid is a well-known artist; and Mr. Edgar Wallace will be recognised by everybody as the war correspondent of the "Daily Mail" and other papers.—"Camera Club Journal" for February.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEMBERS' meeting was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, the 12th instant, at 8 p.m. Mr. Alfred Ellis, President, occupied the chair.

The President opened the meeting by informing the members that the Association had been presented by Mr. H. Edmonds Hull with a chairman's hammer, and he would endeavour to keep order with it that evening.

The Committee's report of the progress of the Association since the annual general meeting was presented.

Mr. Frank Turner asked for a little more information regarding the examination of assistants. Were the Sub-Committee asking the co-operation of teachers at the Polytechnic in any way? He had been informed that they were going to write to the Association to know whether they could help in the matter.

Mr. Coles wished to know whether it was contemplated to hold examinations at once, or was the matter only now being considered. Mr. Mackie informed him that no period had been fixed, but that the Committee were now prepared to invite assistants to apply for certificates on the long service qualification. Mr. Coles pointed out that at present there was a considerable lack of inclination to study or acquire any more information or knowledge than was necessary to take assistants through their daily work, and a step such as that proposed should be welcomed. He found that anything in the way of getting assistants to improve themselves in technical matters was so much waste of breath, and if, therefore, there was an examination that they could point to as some indication of having satisfied skilled photographers of their abilities, it would greatly benefit the assistant as well as the employer.

Mr. L. Langflier said he was very pleased to hear discussion of the members on this matter, which would tend to strengthen the hands of the Committee.

The granting of certificates by the Association would greatly benefit not only the assistants, but the employers, for the reason that the certificates would be a proof that the holder's ability had been put to the test by competent professional photographers. He deprecated any connection with the Polytechnic, and thought that as the Association represented a large body of photographers it was quite capable

of carrying the matter through. The Committee were working very hard, and their labours would show good results.

Mr. Coles thought that they should all assist in getting the members, and that the suggestion of examinations would assist in this direction.

Mr. S. H. Fry asked if it was not possible, in conjunction with the matter, that the Committee might take into consideration the propriety of making some sister Association or Sub-Association, by which the P.P.A. might gain, and from which assistants who had received the Association's certificate might be recruited. Of course, this was a very touchy point, and likely to have great difference of opinion. The point that must be borne in mind is that photography is essentially one of those pursuits in which the assistant, or often the amateur worker of to-day, is the full-blown photographer of tomorrow.

Mr. W. Gill thought there ought to be an examination in every case and that they would be making a mistake to grant a certificate of employers' vouchers only. Before the Association invited assistants they ought to deal with specimens, and go into the matter thoroughly.

Mr. Lankester: It would be a good plan to let members know who were the Sub-Committee. They would then have full confidence.

The names of the Sub-Committee were then read out, viz., Messrs. F. A. Bridge, Martin Jacolette, L. Langflier, H. S. Mendelsohn, Lang Sims, and the officers of the Association.

Mr. W. Coles asked whether a certificate would be granted on the strength of one employer, supposing the assistant had been employed three years. Would they require to know the last employer of employers for the last five years? If a man wished to obtain a certificate, would he have any difficulty in satisfying the Board of his five years' proficiency?

The Chairman then proceeded to reply to the various questions. The members should bear in mind that the Sub-Committee have not been sitting a great time, and that they have not yet perfected a scheme. He thought, first of all, they could start the granting of certificates to assistants of well-known practical photographers. For instance, where it was known that an assistant was a good practical man, such, for instance, as his own brother-in-law, who was as good a photographer as he was, they could not ask him to come up and be examined as they could ordinary assistants. The Association would first of all grant certificates to men whose employers could vouch that they were proficient in particular branches of their profession, upon production of specimens of their work provided that the employer was known as a good practical man. There was an assistant who was recommended by his employer, but whom the Association had doubts about, they would require some further proof of the assistant's ability before a certificate was granted.

With regard to the assistants, they did not mind whether they came from the Polytechnic or otherwise. If they apply for examination the Association would be quite prepared to examine either, but it was not the intention to examine them theoretically, but practically. Unless the examiners were satisfied in proper manner no certificate would be granted. The great advantage would be that when the certificate was granted the assistant would be more likely to satisfy a photographer of his proficiency. As regards his personal character, that was a matter the employer would have to satisfy himself.

Mr. Fry thought they might see from the results of the examinations what sort of assistants were coming up for examination, and then they could consider the question of "Associates," such, for instance, as Associates of the Academies of Music, etc.

Was it proposed to make a small charge to the assistants?

Mr. Ellis: Yes. We don't propose to give something for nothing. Would the expense be considerable? Would it be a large fee?

Mr. Ellis: Not more than an assistant could afford. It was thought it would be about a guinea, but details would be considered later. The examination would be a drastic one.

The adoption of the report was proposed by Mr. Coles, seconded by Mr. Skillman, and carried.

On a question raised by Mr. Skillman as to the advisability of having grades of certificates, he was informed that it was a matter for consideration, but each subject would be taken separately.

Letter read from Mr. George Moore, of Buckfastleigh, re question sulphide of silver assaying, the members being asked if they had any similar experience to the one brought under notice.

Mr. Gill gave instances of differences regarding assaying of precipitate of gold. Two samples, of 100 grains yielding by different means 11 per cent. and 26 per cent. respectively.

The President reminded members that the next meeting would be March 11th, on the occasion of the annual dinner; he hoped there would be a good attendance of members, and that they would bring their wives, or sisters, or daughters with them.

Letter read from Mr. T. C. Turner, of Hull, regretting that he did not be present to read his paper personally. He had sent a specimen of what the "Hull Daily Mail" advertises as a "two guinea portrait for 6s. 6d." The exhibition of this created a great deal of amusement. Mr. T. C. Turner's paper on "Laissez-faire" was then read by the assistant secretary.

Mr. Lankester was very much interested in Mr. Turner's paper and the picture sent. He did not know whether the London members of this kind of competition more than their provincial brethren.

Mr. Gill thought Mr. Turner should be thanked for his paper, which contained such useful suggestions.

Some discussion followed on the question as to whether photographers, other than the holder and taker of the negative, should charge for large photographs, or even copy them.

Mr. Coles thought that some mutual arrangement should be arrived at and that firms on being asked to make copies of photographs should refer the person making the request to the firm which had sent the original. There might be some little understanding, and in the order might be passed over to the original photographer, who would allow the other firm some small percentage.

Mr. Bridge asked whether it was an acknowledged fact that a better result could be obtained from the negative than the print.

Mr. Langfrier: It only meant working up the print.

Mr. Lankester: In small towns photographers do not love one another sufficiently to take a photograph to one another for copying enlarging. As a matter of fact, you can do just as well from a print from the negative.

Mr. Gill: I put on my cards "Copies 25 per cent. extra." No photographer need scruple in taking an enlargement order in the circumstances. So long as it is understood that the customer has no copyright, I do not think we need scruple. Nearly all the prints for copying are old, and generally it would be found the original negative was not in existence.

Mr. Bridge said that when you can get a 12 by 10 enlargement for what you cannot afford to give a proportion of the amount away. (laughter.)

Mr. Langfrier: Mr. Turner has worked very hard, and done marvellously well. Nobody else in the photographic profession could do that they have ever practically prohibited a firm advertising selling cheap enlargements in any town. This Mr. Turner, in conjunction with the Hull branch, had done. If photographers were a little more friendly, and worked more in harmony they would be something to stand upon, and they could then do something for Mr. Turner.

Mr. Fry thought they should be a little more consistent. He contested the marked-down prices in drapers' shops, etc. He had recently been to Manchester, and he was quite sure there were many photographers who had enlargements in their windows which were better than that exhibited and advertised by the "Hull Daily Mail" as a two guinea enlargement for 6s. 6d.

We are inclined to jump on this kind of thing when an important case does it. It is very reprehensible, but every firm does the same thing.

The President said, we cannot object to them making an enlargement for 6s. 6d., but we do object to the statement that it is the duty of photographers to supply at two guineas.

Miss Lena Connell thought there was no harm in copying old photographs, but people went to a good photographer for one or two prints, and then had copies from them made at a cheaper house. This was too bad.

A hearty vote of thanks to Mr. Turner for his interesting and valuable paper closed the proceedings.

A meeting of the General Committee was held at the Royal Photo-

graphic Society, 66, Russell Square, on Friday, February 12th. Present: Mr. Alfred Ellis, President, in the chair, and Messrs. F. A. Bridge, S. H. Fry, H. Edmonds Hull, Louis Langfrier, A. Mackie, E. Scamell, W. Grove (hon. sec.), W. Gill (Colchester), H. C. Spink (Brighton), and P. Lankester (Tunbridge Wells).

The President read a letter from Mr. H. Edmonds Hull asking the acceptance of a chairman's hammer. On behalf of the Committee, he thanked Mr. Hull for his handsome present, and suggested that the donor's name be engraved on the silver band.

Letters of apology for non-attendance were read from Messrs. Lang Sims and Martin Jacolette.

The draft of the report to be read to the members at that evening's meeting was read and approved.

A letter from Mr. H. W. Barnett was read, in which he notified that owing to stress of business he was reluctantly compelled to resign his position as Vice-President and membership of the Committee.

Mr. Bridge proposed and Mr. Hull seconded that his resignation be accepted and the letter acknowledged with an expression of regret.

The draft of the Sub-Committee's report on the forthcoming Exhibition of Professional Photography at Derby was read.

Mr. Bridge thought that the members should be notified as early as possible, and information obtained from them as to whether they intended to exhibit, and, if so, how much wall space they would be likely to require.

The President thought the suggestion a good one, and said he would arrange that a post-card on which this information could be furnished should be sent to each member when sending them the entry form and particulars.

It was agreed that Mr. C. B. Keene, Mr. Scotton, and Mr. Crowder (Curator of the Derby Art Gallery) should be invited to form the Hanging Committee.

The interim report of the Assistants' Examination Committee was read, and, after some discussion, was adopted.

The account from Messrs. Strangeways, amounting to £14 8s., for the printing of handbooks, list of members, etc., was passed.

Letter received from Mr. T. C. Turner, of Hull, apologising for his inability to attend meeting, and requesting that the paper he had prepared might be read at the members' meeting that evening. He also notified having sent a specimen of the "Hull Daily Mail's" enlargements, advertised as being worth two guineas, for 6s. 6d.

Arrangements for the annual dinner were discussed, the dinner to take place at 7. It was agreed that as many members of Committee as possible should be in the reception room from 6 to 7 to receive country and other members and guests.

REPORT, FEBRUARY, 1904.

SINCE the annual general meeting twenty-two new members have been admitted to the Association. Up to the present time 474 members have paid their subscriptions for this year.

The new handbook has now been in the hands of members for some time, and the Committee believe that the pains taken to increase the practical value of the section devoted to private information to members have been appreciated, and that the lucid explanation of the copyright law as affecting professional photographers has been a valuable assistance to many members.

The plague of cheap enlargements unfortunately shows no abatement. In every case that has been brought to the notice of the Committee a protest has been made, but without success, except in a few instances, where the statement has been withdrawn, that the enlargement advertised is equal to one charged so many guineas for by photographers. It is obvious that the Association has no legal means of applying coercion, but that a great deal may be done to counteract the effects of these advertisements locally by combination has been amply demonstrated by the total defeat of the Liebig Extract of Meat Co. at Hull, by the energetic action of the Hull branch of the Association. The Committee consider that the Hull branch has earned the thanks, not only of the Association, but of photographers throughout the kingdom, for their spirited attack. The Committee believe that in many centres the local professional photographers are influential enough, if they could act together, to deal with their enemies with equal success, and any serious attempt in this direction would be most heartily supported from headquarters.

The success of the exhibition of professional photography held at Perth last year during the meeting of the Convention was so great that it was considered advisable to repeat the experiment in connection with this year's Convention, if possible. With a view to making arrangements, our President paid a visit to Derby, and was so successful in interesting Mr. Crowther, the custodian of the Art Gallery, in the scheme that the Corporation has placed the picture galleries at our disposal without charge for a public exhibition, to be open for a month. An invitation to exhibit, and full particulars, will be sent to each member in a week or two.

That important function of the Association, the holding of examinations for photographic assistants, and the granting of certificates of proficiency, is now receiving serious consideration. The Sub-Committee appointed for dealing with the matter have made an interim report, in which it is recommended that certificates without special personal examination be granted to assistants who have been practising for at least five years on the recommendation of those in whose employ they have been. Although the arrangements for holding examinations will necessarily take considerable time to complete, the Committee will immediately proceed to invite applications for certificates under the service qualification.

The arrangements for the annual dinner, to be held at the Criterion Restaurant, on Monday, March 11th, are now complete. As there are several lady members of the Association, and as so many photographers' wives and other female relations are actively engaged in the business, it has been thought a fitting acknowledgment of our indebtedness in this direction that members attending the dinner should be specially enjoined to bring lady guests.

It has been felt by some of the members of Committee that it would be a graceful act to present each President with a souvenir of his year of office. A pair of dies, for the purpose of striking a badge or token, has been presented to the Association, and the Committee are subscribing amongst themselves the funds for providing gold tokens for presentation to Messrs. Thomas Bedding and Wm. Grove, past Presidents, and to our present President.

The Committee regret that they are losing the valuable assistance in their deliberations of Mr. H. Walter Burnett, who is obliged to resign his office as Vice-President on account of increasing business.

PHOTOGRAPHIC CLUB.

FEBRUARY 10TH.—Mr. John H. Avery gave a demonstration of printing on Messrs. Wellington and Ward's bromide paper. The negative for a good print should be also a good one, and with sufficient density, not a thin ghost, which seemed to be the prevalent opinion. The light he used himself and recommended, on account of its constancy, was an ordinary candle. Using a fairly dense negative, 12 by 10 at a distance of 15in. from the flame, an exposure of one and a half minutes was given. On development with Amidol it proved to have been correctly exposed. He had never detected any unevenness when exposing a 15 by 12 negative at 15 in. A large number of slides from negatives made while he was with the Sultan of Morocco were then shown and described by the lecturer, and proved extremely interesting.

CROYDON CAMERA CLUB.

FEBRUARY 10TH.—Despite the inclement weather, a large number of members mustered to hear Messrs. F. W. Hicks and W. H. Rogers give a demonstration on enlarged negatives, respectively on plates and paper. On the previous Wednesday, Mr. Hicks gave some valuable hints as to the production of the preliminary transparency. Chiefly on the ground of expense he preferred to make a small contact positive in the first place, employing either a slow dry plate, such as Wratten's "ordinary," or the special autotype tissue sold for the purpose, and which was practically grainless. For the latter, three and a half times the exposure was necessary, compared to P.O.P. printed to the "pretty" stage. When using the former care should be taken to mark the clear glass edges of the plate, so as to prevent light creeping round. For daylight enlarging the density of the small positive should be comparable with the average lantern slide, but without its brilliancy, perhaps, the best results were obtained with the high lights somewhat veiled. He advocated metal as a developer, as possessing a minimum tendency to block the shadows. A slow plate was best for the enlarged negative, and the

requisite exposure could be found in the usual way on a quarter plate of the same batch.

Whilst projecting the image from a carbon transparency on the easel by means of the club lantern, reticulation markings existing in the original showed up plainly, and subsequently duly recorded themselves. Mr. Hicks said he invariably used daylight, and although reticulations might exist in the positive, they had never troubled him in the enlarged negative, or indeed become apparent. Mr. Rogers then followed, substituting Kodak A. slow bromide paper, and several satisfactory 15 by 12 paper negatives were made. He claimed for them, cheapness and ease of retouching. Microscopic detail was, of course, unobtainable, and not always desirable. The only objection he had heard urged was that the grain of the paper showed to some extent; this might be so, but it was not obtrusive in large work. Rodinal as a developer was cleanly and convenient; he employed it at a strength, 25 minims to the ounce, plus 5 minims of a 10 per cent. bromide solution. He never waxed or oiled the paper negative, and saw no necessity for so doing.

RICHMOND CAMERA CLUB.

FEBRUARY 11TH.—A paper on the capabilities of the X-Rays was read by Dr. Rodman, who for some years has made a special study of this subject. Dr. Rodman spoke first upon radiography, or the production of images upon a photographic plate by the X-Rays, and then upon the subject of radioscopy, or the examination of an object by means of the fluorescent screen. In December, 1895, Professor Röntgen announced his since famous discovery to the Physico-Medical Society of Würzburg, on which occasion he described certain rays which, themselves invisible, are capable of penetrating many substances opaque to ordinary light. This discovery was due to the happy chance of an accidental observation. While making experiments with a Crookes Tube, he noticed that a piece of paper covered with platino-cyanide of barium became fluorescent. The same result was produced even when the luminous tube was enveloped in black paper, and he found that the rays have the power of exciting photographic action and penetrating various substances in differing degrees, roughly speaking, in inverse proportion to their thickness and density of structure. Dr. Rodman then threw upon the screen a photograph of the apparatus required for the production of X-Rays, which he proceeded to describe in detail. His apparatus is worked from a 12-cell accumulator, and he finds that as soon as the charge of electrical power falls to about 19 volts per cell, it is necessary to re-charge it. The apparatus used consists principally of an induction coil and a vacuum tube, with the necessary connections and accessories. The induction coil that Dr. Rodman uses contains about 10 miles of insulated wire in the secondary coil, and he showed upon the screen a photo of a 9-inch spark produced by it, representing a very high voltage—as much as 100,000 volts are represented by a 6-inch discharge. The vacuum tube may be described as the lamp by means of which the X-Rays are produced. It consists of a highly exhausted glass bulb connected to the secondary terminals of the coil. Inside the bulb are two discs, one at each end, that at the negative end, called the cathode, being concave, and the other at the positive end, known as the anode, being flat. When the current is switched on, instead of a stream of sparks passing between the anode and the cathode nothing is seen to pass, but the tube becomes fluorescent, and is filled with an apple-green light. Those are the X-Rays. The shapes of the discs cause the rays to be concentrated and deflected upon the objects to be examined by the fluorescent screen, or radiographed. The fluorescent screen consists of a frame, chemically prepared, sheet of vellum, coated with barium platino-cyanide. The object to be examined is placed between the tube and the screen, the latter being placed with its fluorescing salts outward. In photographing the image, Dr. Rodman found great advantages in the use of rapid plates. Length of exposure depends upon the thickness and opacity of the object to be radiographed, and it is frequently necessary to shade thin or translucent portions to prevent over-exposure during the time required to get the details of the thicker or more opaque portions. Dr. Rodman remarked that it is impossible to foretell what further discoveries are in store for us in connection with the X-Rays. We know that the superficial action of the rays upon the cutaneous surface of the body is considerable, and that at the present time cases of lupus, hitherto incurable, are being treated by daily exposure to the influence of the

s with apparently curative effect, and it is hoped that some forms cancerous growth may succumb to the same influence; but apart from therapeutics, there are many other uses to which the X-Rays may be applied, such as for testing precious stones, Custom House investigations, and doubtless many others will present themselves as the work goes on. Dr. Rodman then proceeded to show a number of radiographs through the lantern. He showed first a number of objects, such as scissors, spectacles, rings, etc., radiographed through cases in which they were contained, various animals and reptiles, showing their internal anatomy, and a very fine collection of shells, in which the structural details and markings were very clearly indicated. Radiographs of diamonds showed them as perfectly transparent, whereas paste diamonds were opaque, owing to the large quantity of lead used in their composition. Other precious stones showed the real stones to be more or less translucent, the imitations intercepting most, if not all, the X-Rays. Pebbles, rock crystal, and glass were compared, and showed more or less marked difference in translucence. After these Dr. Rodman showed radiographs of surgical cases, such as needles and bullets imbedded in the flesh, cases in which the X-Rays have been used as aids to diagnosis, prognosis, and treatment, such as fractured and splintered bones, dislocations, and growths, and he concluded by showing some curiosities, such as a boy's foot with an abnormal number of bones, the effects of rheumatism, etc.

SOUTHAMPTON CAMERA CLUB.

FEBRUARY 15TH.—Lecturette Competition.—Each contributor was allowed ten minutes to render his discourse to illustrate, which not more than eight nor more than twelve lantern slides of his own production were allowed. The contest was a good one, the competitors being Messrs. Walton, F. G. Ryder, A. Copeland, W. R. Williams, and J. Evans. The winner was decided upon by the votes of the members present, and their choice fell on Mr. Williams, who took for subject "A Visit to the L. and S.W. Railway Company's Works at Eastleigh," of which he gave a very pleasing and graphic description, and produced an excellent set of slides representative of the various departments of these important manufacturing works. Mr. Williams was awarded the club's certificate of merit. Mr. Evans took second place with an instructive discourse on Salisbury Cathedral, and some of his slides were of an excellent quality.

DERWENT VALLEY PHOTOGRAPHIC SOCIETY.

The president's competition was brought to a close at the end of January, and the judge's awards have just come to hand. The competition was for members of the Society only, and the conditions were that each competitor should send in six prints any size up to and including half-plate, and of any subject, finished in any process and mounted. The sum of £5 was generously given by the president (Mr. R. Williamson, South Lodge), and this the committee divided into four prizes. In order to encourage beginners and place them as far as possible on an equal footing with more advanced workers, competitors who had commenced photography within two years of the date of the opening of the competition were given an allowance of marks. The judge was Mr. P. R. Salmon, editor of the "Photographic News," who fixed the maximum number of marks at 20, giving an allowance of five in each case to the beginners who had made it, these being marked * in the following list of awards:—1st, £2 10s., Mr. J. T. Robinson, 20 marks; 2nd, £1 5s., Mr. A. C. Pen, 18; 3rd, 15s., Mr. P. M. C. Eden, 17; 4th, 10s., Miss F. L. (Loweswater), 16. The other competitors are placed in the following order:—Messrs. C. Armstrong, B. Green, and J. Dallas*, each; R. H. Williamson, 14; J. W. Wood*, 13; J. R. Bleasdale, 12; W. H. Lewthwaite, 10 each; R. Williamson, 9.

The judge's remarks are: "On the whole the work is good, but painting seems poor. Mr. Robinson's work is excellent, also Mr. Pen's. These two are a long way ahead of anyone else. Mr. Pen's allowance of five brings him next." The prizes were handed to the successful competitors at the Studio, Cockermouth, on Monday night by Mrs. J. W. Watson. Hearty thanks were accorded Mrs. Watson, the editor of the "Photographic News" and the president, who repeated his offer of £5 for prizes for future competitions.

Commercial & Legal Intelligence

HELIOGRAVURE COMPANY, LTD.—This company has been registered with a capital of £2,000 in £1 shares. Object, to carry on the business of photographers, lithographers, engravers, etchers, etc. No initial public issue. Registered without articles of association. Registered office, 78a, Mosley Street, Manchester.

BIOPHONE COMPANY, LTD.—The above-named company has been registered with a capital of £20,000 in £1 shares. Object, to adopt agreements (1) between the shareholders of the Kuvverin Phonograph Company, Ltd., of the one part and E. M. Davey of the other part; (2) between H. Fairbrother of the first part of Tourtell Gas and Engineering Company, Ltd., of the second part and the said E. M. Davey of the third part; and (3) between J. M. Tourtell and G. L. Hogan of the first part, the Tourtell Manufacturing Company, Ltd., of the second part, and to carry on in the United Kingdom or elsewhere the business of manufacturers of and dealers in talking machines, gramophones, phonographs, biophones, and similar instruments, etc. No initial public issue. The first directors (no number not less than two nor more than seven) are to be appointed by the signatories. Qualification £250. Remuneration as fixed by the company. Registered office, 18, Fleet Street, E.C.

BEFORE Sheriff Henderson Begg—in Aberdeen Small Debt Court—a case was heard in which Alfred Margand, trading as the Universal Portrait Company, 12, George Street, Aberdeen, sued a fisherman residing in Victoria Road, Torry, for 16s. 6d., being the balance of the price of an enlargement of a photograph and a frame supplied by the pursuer at the price of 18s. 6d. Mr. John Croll, solicitor, appeared for pursuer, and Mr. H. C. B. Forsyth, solicitor, for defender. John Schindler, assistant, Universal Portrait Company, said he had called upon defender's wife and sold her the frame for 18s. 6d., of which she paid 2s. An agent of the company had previously called upon her and obtained a photograph of her daughter to enlarge. They enlarged such photographs very cheaply, in order that people might show them to their friends and thus advertise their work. The Sheriff: Is it not the case that you do it cheaply in order that you may get an order for the frame, and there you will thus make up for any loss on the enlargement? Witness: No. The Sheriff: Do you go in for this business through amiability?—(laughter). What is the frame really worth? Witness replied that it was worth about 12s. 6d., but they had expenses to meet in connection with it, such as carriage, delivery, and so forth. Margand, in the witness box, said his method of business when he went to a new town was to send round a circular asking people if they had any photographs to enlarge. They would do enlargements free of charge, but if the people wanted the photos completed they must buy a frame. Is all that told at the first interview?—(laughter). Witness: Yes. Other evidence having been led, the Sheriff assoilized defender, with expenses, holding that as the photo was not a necessary the husband was not liable for what his wife had ordered. In five other actions by the same company the defenders were assoilized on the same grounds.

Commenting on the foregoing case "The Aberdeen Evening Gazette" remarked:—The decisions given by Sheriff Henderson Begg in connection with the actions brought by the Universal Portrait Company should be of practical service in two directions. In the first place, they make it known that as portraits are not necessities, husbands are not liable for them when ordered by their wives. That is a fact well worth knowing, seeing that it is a plan increasingly in vogue with certain portrait and other canvassers to make their calls at citizens' houses when the husbands are absent, and when they think their plausible stories will go better down with the "guid-wives." In the second place, the decision should be a warning to people against the portrait enlargement dodge. That dodge is a very transparent one, and yet there always seem to be hundreds of gullible people who are all too ready to rise to the bait. The offer is to do enlargements almost for nothing. The agent of the company concerned in the actions brought forward yesterday said "they enlarged such photographs very cheaply"—indeed, enlargement is generally offered to be done for next to nothing—"in order that people might show them to their friends, and thus advertise their work." That is nonsense. The enlargement business could not stand on its own legs at the rates that are dangled before customers'

eyes. As a rule, the idea is to get customers for enlargements by encouraging the belief that something very like philanthropy is being extended to them, and then to press upon these customers—often very much against their wills—the purchase of frames. But for the prices charged for these frames, the photographic enlargements could not be offered at the cheap rates current with the class of enlargement dealers referred to, and there are cases galore of people finding the utmost difficulty in securing enlargements without frames or without some increase on the rates under which they were induced to give their orders. In one respect people have themselves greatly to blame. Nothing could be expected for nothing in these days, and good photographic enlargements cannot be procured unless by paying the reasonable prices that are charged by ordinary (as distinguished from the “free enlargement”) photographers.

X-RAYS IN COURT.—A case of considerable interest arising out of the application of the Röntgen rays was concluded in Dublin on Friday last, before Mr. Justice Gibson and a special jury. The action was brought by a Galway bookseller, named McCullogh, against the Galway Queen's College, and against Dr. Colohan, as his medical adviser, and a man named Haire, as the Röntgen ray manipulator of the College, for damages for the negligent and wrongful application of the rays to his son's knee. It appeared that the boy, who was aged seven years, stated that a needle had entered his knee and got broken, the head remaining inside. In order to discover its location the rays were prescribed first by direction of a Dr. Quirke, of Galway, now deceased, and subsequently by direction of Dr. Colohan. The latter is a doctor in connection with the Galway Queen's College and the Galway County Hospital, which institutions have a working connection. The rays were kept in the Queen's College for educational purposes, but a practice had grown up of allowing the man in charge, Haire, to take radiographs for doctors in Galway. In the present case the radiographs were taken by Haire, who, on the advice of the president, personally charged a fee for taking the plates, and for the work a cheque was sent to the President, and endorsed and given by him to Haire. The boy's knee was exposed to the rays six times in December, 1902, but the needle was not localised. The knee got ulcerated later on, but in April, 1903, it was, by Dr. Colohan's direction, radiographed four or five times again, but the needle was not detected. The boy was then sent to Dublin, and an X-ray expert, on seeing the knee, refused to use the rays upon it. A severe burn, or dermatitis, broke in on the boy's knee, and this caused him considerable suffering. It was now healed, but medical evidence was given to the effect that it might break out again. For the plaintiff it was stated that the X-ray operator had placed the X-ray bulb within two or three inches of the boy's knee while he was taking the radiographs, and the exposures varied from twenty to thirty minutes. For the defence, the witnesses said that the bulb was not held within a lesser distance than six or seven inches. A great number of expert witnesses were examined on both sides, and in the result the jury found for the defendants on the general issue that there was no negligence.

THE Annual Dinner of the Hackney Photographic Society was held on Tuesday last, February 16th, at the Great Eastern Hotel, Liverpool Street, E.C. The President, Mr. J. O. Grant, was in the chair, and he was supported by nearly a hundred members and visitors, among the latter being Rev. F. C. Lambert, Mr. Alexander Mackie, Mr. Thomas Bedding, F.R.P.S. (Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*), Mr. H. Snowden Ward, Mr. H. W. Bennett, F.R.P.S.

MORE Scheduled Poisons Suggested.—In a lecture on “Poisoning in its Medico-Legal Aspects,” delivered in the Old Hall, Lincoln's Inn, by Dr. Waldo, the City Coroner, on Thursday, last week, the lecturer said that he agreed with Dr. Wynn Westcott in recommending the addition of strong mineral acids, ammonia, and certain other poisons to the scheduled list. We do not know what the “certain other poisons” are; but there are many poisons used in photography that are not at present scheduled—pyrogallie acid, and some of the new developers; nitrate of silver, sulphate of copper, etc., for example. If such things as these were scheduled, and could only be purchased from pharmaceutical chemists, photographers would have to pay more for them than they now do to the photographic dealers. However, they are not yet scheduled, and there is but little prospect of their being so in the very near future.

News and Notes.

ROYAL Photographic Society.—At the Technical meeting to be held on Tuesday, February 23rd, at 66, Russell Square, at 8 p.m. Mr. T. E. Freshwater, F.R.M.S., will read a paper “On the History and Lighting of the Magic Lantern.”

SOUTHEAST-ON-SEA PHOTOGRAPHIC SOCIETY.—Owing to pressure of business the Hon. Sec., Mr. A. J. Langridge, is obliged to resign his post, which has been accepted by Mr. John Archer of 24, Ashburnham Road, Southend, to whom all communications should be addressed in the future.

THE “Standard's” Berlin correspondent, telegraphing one day last week, said:—Professor Henri Dufour and M. Held, an engineer both of Lausanne, who have been experimenting with radium, have said to have established the fact that radium rays are capable of penetrating a polished granite slab about 2 ft. thick, and steel plate one centimetre thick. This experiment was carried out by means of highly-sensitised photographic paper.

NEW Magnetic Observatory.—Since the magnetic observatory at Kew was rendered unsuitable by reason of the proximity of electric lines, etc., the authorities have been looking out for a more suitable site. This has now been found on the ground purchased by the Government from the Duke of Buccleuch in the parish of Eskdalemuir, Dumfriesshire, for the purpose, and upon which the surveyors report favourably. Building operations are to be commenced shortly, and it is thought they will take about four years to complete. To find a suitable situation for a magnetic observatory in these progressive times, that will be suitable years hence, has been no easy matter, seeing that the observations are affected by far distant electric currents, such as those in lighting or traction cables, telegraph or telephone wires, etc. The site selected seems very suitable for its purpose. It stands high and dry in a pastoral and hill district, and is quite remote from railways; the nearest being about fifteen miles off. When reading this description of the locality of the new observatory, one is inclined to wonder whether the employees in it, considering the monotonous character of their work, will find the place a cheerful dwelling all the year round. Personally, we are not inclined to envy them.

WINTER Pictures.—Photographers resident in the home districts have this year had but scant opportunities of obtaining pictures of winter scenes, unless, indeed, flooded districts can be classed as such. As the season is so far advanced, there seems to be but little prospect of our having much, if any, snow, and if we do have some the sun is now getting such power that it must not be expected to last very long on the ground; hence, those who desire to secure wintry effects should be on the alert to secure them directly the opportunity occurs, as it will, in all probability, be but of very short duration. However, although the outlook for obtaining snow pictures is now very poor, there is ample time to secure good pictures of hoar frost effects. Hoar frosts often hold well into the spring, but the best effects with them are very transient in nature, for soon after only a few minutes after the sun shines upon them, they are gone. Therefore those who desire to secure pictures of them must be on the look-out, keeping their slides ready filled with plates, or a fresh spool in the camera if roll films are used, ready for exposure the first morning the hoar frost appears. It is needless to say that to secure the best negatives of hoar frost, as with snow, the plate should be backed to avoid halation. As for subjects with hoar frost they are almost everywhere. An unpretentious back garden covered with hoar frost makes an excellent picture for the lantern, and is usually much admired when projected on the screen. In some cases a heavy hoar frost on the grass and trees will pass as a snow picture for the white rime conveys very much the impression of a slight fall of snow.

RADIO-TELLURIUM.—A new radio-active substance is said to have been discovered by Prof. Dr. Markwald, of Berlin. Speaking at Vienna, the Professor said that in experimenting with pitchblende (oxide of radium) from Joachimsthal, Bohemia, he discovered minute quantities of a very active substance which he has named radio-tellurium. At first it showed all the reactions of tellurium, but further examination proved it to be a mixture of tellurium and minute quantities of a substance hitherto unknown. The quantity

radio tellurium contained in pitchblende is much smaller than that of radium, the proportion being about one in a milliard, which is less than the quantity of gold in sea water. Radium gives off three kinds of rays—Delta rays, hardly penetrating solids at all; Beta rays, moderately absorbed by solids, and powerfully deflected by a magnet; and Gamma rays, difficult of absorption and not deflected. Radio-tellurium, however, gives off only Alpha rays, which the Professor showed, will pass through a very thin sheet of aluminium, but not through a sheet of paper. Alpha rays possess to a high degree the power of making air a good conductor of electricity. Prof. Markwald, to show the remarkable properties of radio-tellurium, placed a copper plate with electrolytic precipitation of the new substance, consisting of some hundred-thousandths of a millimetre, near a set of electric chimes, and it stopped them. When he put near a Leyden jar it caused it to discharge through the air without emitting sparks. Then the Professor attached an electric wire to a wire and the other end of the wire to this copper plate. When he put a condensing machine near, and when he set it in motion, electricity passed from it through the air to the plate, and thence through the wire to the bell, which it set in motion, although it was directly connected with the machine. But a sheet of paper held between the air between the machine and the plate interrupted the current, so that the bell ceased ringing. Speaking of other radio-active substances, Prof. Markwald stated that salts of radium shine spontaneously, that being specially the case with a rapidly-dried mixture of bromide of radium and bromide of barium; but radio-tellurium does not.

The Scottish Photographic Federation.—Secretary's report, 1903. The Scottish Photographic Federation was formed at a meeting held in the rooms of the Perthshire Society of Natural Science, Perth, on January 17th, 1903, when twenty-seven delegates were present from fourteen societies. A sub-committee drafted rules, and at a meeting on March 2nd, these rules, which had been previously circulated amongst the societies, were the subject of much discussion, and were duly adopted with alterations. The officers were elected, and the work of the Federation really set on foot. It was intimated at this meeting that sixteen societies had decided to federate. The first meeting of the Council was held at Perth on May 2nd, when something was done to provide benefits for the federated societies. Arrangements were made for a list of lecturers, etc., and judges were appointed—the majority of these having agreed to act. It was decided at this meeting that the Federation should promote an exhibition at Perth on the occasion of the first annual general meeting, and a committee was appointed, with full powers to carry this decision into effect. The next Council meeting was held at Stirling on September 5th, when the lantern slide rules were discussed and adopted, and the Secretary instructed to have these, and the list of lecturers, etc., which had been composed, printed and circulated. On December 19th the Council met at Glasgow, when judges were appointed for the lantern slide competition, and arrangements made for the opening of the exhibition. A record of work accomplished by the Federation, especially when considering the time spent on the necessary initial arrangements, is, I think, praiseworthy. The list of lecturers, demonstrators, circulating lectures, and lantern slides, as well as the list of judges, though issued after many of the societies had made their arrangements for the session, were well taken advantage of, no fewer than 150 applications having been made for these. The lantern-slide competition—the prizes for which, it may be mentioned, were given to members of the Council—has been well supported, 268 slides being sent. The exhibition opened to-day—the Scottish National Salon marks a distinct innovation in photographic exhibitions. There is no need for me to speak of its success, you have seen it for yourselves. At least three exhibition-promoting societies have included their prospectuses a class confined to associates. I hope this spirit of camaraderie will be supported. The Federation at its formation consisted of sixteen societies, now twenty-three combine to work for the betterment of Scottish photography, and I hope the time is not distant when every photographic society in Scotland will federate, a matter of course. The stronger the Federation, the more benefit will be its work, and its record for the first year of its existence shows conclusively that it will be a power for good to all British photographers.—John B. MacLachlan, secretary.

Correspondence.

THE NEW DYES.

To the Editors.

Gentlemen,—In the current number of your valuable publication there is the second and concluding portion of a translation from "Das Atelier des Photographen" of an article by Baron von Hübl, entitled "A New Collodion Emulsion." Among the coloured sensitizers recommended for the emulsion there is p-toluchinaldin-chinolin-methyl cyanine, as giving in a degree hitherto unattained sensitiveness to the blue-green. Now, in the "Process Photogram" of September last there appeared Valenta's report on this dye, translated from the June number of "Photographische Korrespondenz." The following is the translation:—

"On short exposure one obtains a band from B₄C to h, in which is to be seen a maximum at D, an indistinct minimum at D₂E, and a further maximum at D₃E. On longer exposure the action extends to B and further."

Valenta's report is on the effect which the dye produces on gelatine plates, and it will be noticed that nothing is said about the blue-green region of the spectrum. But in the same article there appears a report on the ethyl compound of this dye, viz., p-toluchinaldin-chinolin-ethyl cyanin, and, according to the translator, Valenta says of it:—

"This dye is very similar to the methyl compound, but renders the blue more strongly. With medium exposure, a maximum is to be found at F, and the action does not extend so far into the orange red."

It is remarkable that the "Photogram" translation of Valenta's report ascribes to the ethyl compound the very property which is claimed for the methyl in your translation of Hübl's article. When I first read the "Photogram" statement that a maximum appeared at F, I concluded a mistake had been made somewhere; either "maximum" had been printed for "minimum," or F for E. Your translation of Hübl's article merely increases my perplexity, and you will confer a great favour upon me if you, or any of your readers, will clear the matter up. Perhaps you have the June number of the "Photographische Korrespondenz" by you, and, in that event, you might have the goodness to give an exact translation of what Valenta says on both the ethyl and the methyl compounds. I fear I am trespassing somewhat audaciously on your goodness, and if I were not aware how much your patience is exercised weekly with questions which ought never to be asked, I should sink back diffident and silent. If you will publish an answer, however, I feel sure you will do a service to many besides myself, who are interested in tri-colour photography.—Yours faithfully,

INQUIRER.

February 8th, 1904.

[Our correspondent's difficulty is very easily explained away. The translation in our contemporary is correct. Baron Hübl's experiments were made with collodion emulsion, whilst Valenta used gelatine plates, therefore the results are neither comparable nor contradictory. It very frequently happens that a dye may be an excellent sensitizer for collodion but utterly useless for gelatine emulsion; a notable instance of this is ethyl violet, which acts well with collodion but is quite useless for gelatine. Another point which must not be lost sight of is that Hübl used chloro-bromide of silver; Valenta, on the other hand, in all probability bromoiodide, and even in the same vehicle a difference of sensitising is then frequently to be noticed. Further, a difference is to be observed in the opacity of maxima and minima when the prismatic and diffraction spectrum is used. Another source of apparently contradictory results may actually lie in the varying proportion of iodide to bromide of silver, and whether the dye is added to the emulsion before coating, or the plates bathed in a solution of the dye, whether free bromide or an alkali is present, and whether the plates are washed after bathing. As a matter of fact, the whole subject is so complicated that

generalities alone can be stated, and spectroscopic tests should always be averaged for practical work by pigmentary charts.—Ed., B. J.]

FIFTY YEARS AGO.

To the Editors.

Gentlemen,—Referring to your articles, "Extracts from the 'Liverpool Photographic Journal,' the Organ of the Liverpool Society," of fifty years ago, it may be of interest to the numerous readers of your valuable journal to know that Mr. J. A. Forrest, whose name was so prominently associated with the very earliest recollections of the journal, still takes a lively interest in matters photographic. At the enormous age of nearly ninety years he is, doubtless, the only survivor of those whose names occur in these very early records, and he is still a honorary member of the Liverpool Society.

He has expressed his pleasure in seeing these articles reproduced in which he has been very interested, and has a lively recollection of the events.

The photograph of the moon in connection with the British Association's premium offer, taken by Mr. Forrest in conjunction with Mr. Hartnupp (of the Bidston Observatory), was at that time probably the most successful one ever obtained; he still treasures this negative, and is always delighted to show it to his photographic acquaintances.

His experience in the wet collodion process, and his associations later with Mr. B. J. Sayce—also connected with the Liverpool Society—are interesting to relate, and the amount of enjoyment he has derived from amateur photography in his early days, and in interesting himself later in all new developments in the photographic art, is incalculable, and to the present day he takes pleasure in any new process or invention.—Yours truly,

S. H. SAUNDERS,
Member of the Liverpool Amateur
Photographic Society.

February 13th, 1904.

COLOUR VISION.

To the Editors.

Gentlemen,—With regard to Mr. Harry Quilter's criticism of my suggestions on the evolution of colour vision in man, I think he builds too big a castle on a somewhat shifty foundation. If man of the Stone Age had left coloured paintings, or even a bit of crude pottery ware with a rough design in one colour, then one would say beyond doubt he had colour vision. But to assert that because other animals, either contemporaneously or ages previously, had developed colour sight, therefore man had the same power, is making too free with the theory of evolution. That butterflies, which belong to a side chain, had developed colour-seeing eyes, is no proof that the main trunk line had acquired the same power. And, even if it had, it is conceivable that in the enormously long interval before man appeared, colour-vision might have been lost for awhile, owing to its inutility under new circumstances, and afterwards regained. Nature has her retrograde movements as well as progressive. However, I had not overlooked the possibility of colour vision having been developed quite early in evolutionary ages (when writing my article), although I did not know about the butterflies; but for the sake of simplicity, as it seemed to me, I avoided the reference. But even if it be a fact that colour vision was developed in the dawn of life, and has continued without a break to the present time, does this destroy my argument in principle? I do not think so. Rather has the ground been merely shifted from one point of evolutionary time to another, and at the same time my plea for a simpler theory of colour vision than those now in vogue has, perhaps, been strengthened. For Nature, like man, needs experience in her work before she can turn out the perfected article. In the dawn of life, crude forms, imperfect organs; in the ripeness of experience, highly-developed man, finely-wrought organs. If, then, the crude insects of the beginning of time could distinguish the colours of Nature with their imperfect eyes, what need of the complicated mechanism required by the three-sensation theory? Is it likely that the red-green and yellow-blue substances of Hering could have been developed at this early stage?—Yours, etc.,

February 17th, 1904.

"FESTINA LENTE."

A CORRECTION.

To the Editors.

Gentlemen,—In your report on my paper on the metric system there is an error which has escaped correction, and which I would ask you to kindly let me correct. In the last paragraph, fifth line, the wording should be "measurements that are *not* entirely incomprehensible etc. This will put the sense of this paragraph right.—I am, yours truly,

J. R. GORZ.

215, Shaftesbury Avenue, London, W.C.,
February 12th, 1904.

THE SOUTH LONDON PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the Editors.

Gentlemen,—I understand that the Cripplegate Photographic Society have extended the last day for entries for their exhibition and as we have arranged with them to collect from their exhibitors any pictures entered for both exhibitions, we shall have to extend our closing time in a similar way. I have been thinking over the matter, and after consideration of the work to be done in compiling the catalogue, I have decided to so arrange matters that entry form reaching me up to Thursday, February 25, will be included in the catalogue. I trust that this practice of altering the dates for closing may not increase, as it rather upsets one's calculations of working time for compilation of the catalogues.—Yours faithfully,

W. CALDER MARSHALL, Hon. Secretary.

41, Glenton Road, Lee, S.E.,
February 12th, 1904.

RADIUM Solutions.—Radium and actinium were discussed recently before the Technology Club of New York in the operating rooms of Dr. William J. Morton, by Dr. George F. Kunz and Dr. Morton, who is professor of electrotherapeutics in the New York Post Graduate Medical School and Hospital. Dr. Morton said: "The Röntgen ray has been of immense value in curing cancer, but radium promises to go far ahead of it. If we had radium of 150,000 activity we could no doubt do a great deal more than we are doing now. Most of it have been confined to a much lower radio-activity. We have been working with from 7,000 to 10,000 luminosity. The actual glow of radium does not represent its actual radio-activity. There is a great difference in the ore. One sort of radium may possess a high luminosity, while another sort may have a high radio-activity and very little luminosity. We cannot boast of the luminosity of the kind which we now have." Dr. Morton startled his hearers by telling of a mixture which he had prepared and called "liquid sunshine," the name having been applied because the doctor regarded it as a good "catch" phrase to give to the preparation. By means of this fluid, he said, the whole interior of a patient could be lighted up. The doctor exhibited six tubes containing "liquid sunshine," one of which, he explained, contained quinine sulphate which had been exposed to radio-activity. He then proceeded to show the luminous quality of the fluid by placing each tube before a strong X-ray whereupon a spot of faint light was seen about the size of the palm of the human hand. "That," said the doctor, "would be the result if the liquid were taken inside. I believe," he added, "that radium may, after all, be the real curative property which has been found in so many spring waters throughout the world. The advantage of radium over the X-ray is that it can be applied directly to the part affected. For example, if placed in a small tube, it may be inserted in the throat, and in similar manner it may be applied to any vital region. In other words, with radium we shall be able to get at the seat of diseases. There is no end, in my opinion, to the cures which may be effected by radio-activity, excited in one way or another. In imparting radio-activity to liquids, however, we have to be extremely careful, and physicians will need to use the utmost discretion in advising patients to drink the fluid. It will be possible, however, to bathe a patient's entire interior in violet ultra-violet light as the result of this discovery, and this light have decided to call 'sunshine.' We know of the value of sunshine on the outside, particularly where bald heads are concerned, and I believe it will have a similar effect on the inside."

Answers to Correspondents.

All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Edward, 13, Bank Street, Edinburgh. Two Photographs of a Room covered with Postage Stamps.

James, Castle Hill Studio, Mere, Wilts. Two Photographs, "Meet of the South and West Wilts Foxhounds."

Jenkins, 316, Victoria Street, Great Grimsby. Photograph of the Theatre Royal, Great Grimsby.

Lovatt, 6, Water Street, Todmorden, Yorks. Photograph of Cricket Field with Spectators.

Evans, 12, St. Helen's Road, Swansea. Photograph entitled, "Washing Day."

H. Balmain, 69, Shandwick Place, Edinburgh. Photograph of Miss K. Mathias, Two Photographs of Messrs. Le Clerg and Dixon, Photograph of "Snooze's Band," and Photograph of Messrs. Greil and Grey, all in "Cinderella" costume, at the Royal, Edinburgh.

Art, Thistlebank, Helensburgh, N.B. Three Photographs of the Rev. A. Allan.

WANTED.—WEBER (Bolton) asks: "Would you be so kind as to give name of book giving the different processes of transferring photos to stone for litho artists?" In reply: "Photolithography," by G. Fritz. The book may be had through any of the dealers.

TS.—"LEO" says: "Can you kindly tell me where I can buy negatives for double printing, ovals, etc., as card enclosed?" In reply: We do not know if this particular mask is on the market. But you might inquire of some of the large dealers, such as Houghton's. You could easily make similar masks by applying water colours on thin paper.

VING HYPO FROM PAPER.—"LAD" (Tufnell Park) asks: "Will you kindly let me know if it is possible to remove all traces of hypo present in paper which is used in the manufacture?" In reply: Soaking the paper in a solution of hypochlorite of soda will destroy the hypo; but of course that treatment will disturb the surface of the paper. It will require a thorough washing to rid it of the hypochlorite after treatment.

PLAY.—We do not quite see what you have to complain of. Many stationers publish picture post-cards, views of the surrounding neighbourhood. You can do the same if you choose. Is there any reason why stationers should not become photographers if they like? As to the question of discount, you might bring that matter before the Professional Photographers' Association, if you are a member of it.

ING SILK.—A. E. H. SMITH writes as follows: "In your query columns of the 5th 'Vulcan' wishes to know where he can procure bolting silk. Probably the following information may be of help to him. He can obtain the silk in question, either coarse or fine, from Kodak Ltd., who keep a stock of same, or any photo dealer will get it for him. Price of same, 23 by 17, is 4s."

RIGHT.—W. MARTIN says: "I have come into possession of a very old photograph, which I should like to copy, but would like your opinion first. It bears the following inscription: 'From a Chalk and Charcoal Drawing, by J. McIntosh, Rochester, N.Y., U.S.A. 1871. Copyright secured.'" In reply: As the picture is an American production the probability is that there is no copyright in it here, as America is not included in the Berne Copyright Convention.

BROMIDE PRINTS.—"W. S." asks: "How are those small bromides done similar to those that were at one time given away in packets of Ogden's cigarettes? They are done by a Birmingham firm at 2s. 6d. per dozen, with name of firm at bottom, in place of the generals' names that were on Ogden's." In reply: They may be done in the following way: Mount, say, a cabinet print on a white mount, and write on the name. Then copy it, several on a plate, with a repeating back camera. Cameras for the purpose are supplied by all the large dealers.

BOOKS WANTED.—A. CORLLIER asks: "Would you please tell me which are the most serious books on following subject?—(1) Three-colour photography (theory) and theories on Maxwell's curves and fundamental colours. (2) Has not Sir W. de W. Abney published any books on the subject? I should like most scientific works (3) Please also note editors of books" In reply: (1) "Photography in Colours," by Bolas, Tallent, and Senior; "Three-Colour Photography," by Hubl. (2) Not that we are aware of. See his Traill-Taylor lecture in the issue for January 22. (3) The editors' names are given above.

ORTHOCHROMATIC SCREENS.—G. BRODIE asks: "Can you let me know if any make of orthochromatic plates, easily obtained in this country, give accurate results with Carbutt's colour filters? I am aware they are stated to be accurate with Carbutt's plates, but as these plates are almost (if not entirely) unobtainable I would be glad to know of any British plates that will suit them." In reply: We have not tried Carbutt's colour filters with English plates, but probably they would answer. We should advise our correspondent to obtain samples of different English plates and try them with the screens, or use those supplied by the English plate makers to suit their plates.

BLUE EYES—LANTERN.—"IVANHOE" asks: "(1) Would you kindly inform me whether, when photographing people with blue eyes, it is better to use iso. plates, as I find they do not show up at all well? (2) And would you also tell me the cause of overheating my limelight lantern? I do not have any excess of hydrogen, and my lantern is as ventilated as possible, yet my slides are often scorched and condenser cracked." In reply: (1) There would be an improvement by using isochromatic plates if they were employed with a pale yellow screen. (2) The only remedy is to secure better ventilation through the lantern, so as to carry off the heat. Try increasing the height of the chimney, at the same time increasing the ventilation at the bottom of the lantern.

STUDIO PAINTING—GAZING SHADOWS.—"COLCUR" asks: "(1) What colours do you recommend for painting interior of studio? My studio has a tendency to give dark shadows rather than otherwise. Personally, I prefer a warm, homely appearance about a studio. (2) What do you recommend to use for black shadows in working up enlargements—namely, to produce touches of black glossy appearances? Dull black does not show up like a glossy black. I find plain gum Arabic has a tendency to dampen and turn mouldy on the print." In reply: (1) A French grey or a pale neutral green will be very suitable. (2) There is nothing better than a solution of good gum Arabic. If it be used fresh there is little risk of its becoming mouldy on the print, unless, indeed, it is kept in an abnormally damp place. In future write on one side of the paper, please.

STAINED NEGATIVES.—"SCOTTY" says: "We have received six dozen 1/2-plate negatives from a customer, which are very badly silver stained. Could you give us any information how to remove them? The negatives are not varnished, and, we are told, were developed with pyro-soda developer. The silver stains were caused with leaving prints and negatives in presses several nights in succession and damp paper." In reply: If the stains are deeply in the film it is doubtful if they can be removed, but you might try a long soaking in a freshly made solution of hyposulphite of soda. If they are merely on the surface, they may generally be removed by rubbing them over with a tuft of cotton wool, charged with a weak alcoholic solution of iodine, about the colour of sherry, until they disappear, and then refix in hypo.

PHOTOGRAPHING INTERIOR.—"DARKNESS" asks: "Will you kindly give me your opinion as to the best way to photograph the enclosed? The light comes from a sliding (open) roof only."

There is electric light in the place, but that seems to me useless. I send you two photos, one taken with electric light and one with magnesium wire, used in the top of building only. Do you know of a way of lighting the top part of the building, which is beautifully painted? Only the ground on which the paintings are executed is a gold one, and comes out so badly, but when you see it lit up at night it is most beautiful." In reply: The only suggestion we can make is that you imitate, as much as possible, the lighting as it appears at night, either by projecting an arc light upward or by using magnesium wire. Possibly a flashlight might aid you. As the ground work is yellow you would find orthochromatic plates useful.

STUDIO.—"GLOSTER" says: "I am about to build a studio, and should like to have your advice. Do you think the enclosed plan suitable for studio and reception-room, etc., the measurements of which are as follows:—Studio 24ft. long, 13½ft. wide, 8ft. high to eaves, 11ft. 6in. to highest part of roof, 8ft. of top and side light, 4ft. blocked at sitter's end? What I should like to know (1) is plan suitable? (2) Is top and side light sufficient? (3) Is 4ft. blocked out at sitter's end sufficient? (4) Would end section as plan be better than full span roof? (5) Would good Eury-scopic lens be suitable for studio work? (6) Having a full unobstructed light on south side (a wall being on north side), what colour blinds would be most suitable?" In reply: (1) Yes, quite. (2) As the studio is 13½ft. wide, another foot of top and side light would, at times, prove convenient. (3) Another six inches, or a foot, might well be blocked out. (4) Yes, as you would get no light on the north side. (5) Yes, though it would be slower in action than a portrait lens. (6) We should recommend two sets, one white and the other dark blue, or light green, to use as occasion may require.

STUDIO QUERY.—"GILLIES" says: "I am making a studio in a town where property is of great value, and necessity compels me to use the ground floor rooms as reception, etc., ones, and the first floor, two rooms, by knocking partition wall out, as a studio; room will be 20ft. long by 19ft. wide, and about 11ft. high. I think of taking 16ft. or 18ft. of the side wall out, from about a foot of the floor up to as near ceiling as the girder, that is to be put in to support the above floor and ceiling, will allow, thus having about 18ft. by 10ft. high of side light, glazing same with ground glass. Do you think I shall have a sufficiency of light, please? Should have preferred the rooms above, but it would encroach on another portion of the building. I could not get any more than 20ft., and there are two or three large stone gables would have to come down, and make alterations more expensive. Work will be mostly cabinet heads and three-quarter figures, thus using sufficiently long focus lenses for the purpose." In reply: Very good portraits can be taken in a studio such as that proposed. It will do well for busts and three-quarter lengths, but will be short for full lengths and for groups. But as the length cannot be increased there is no help for that.

COPYRIGHT.—"VIATYPE" asks: "Will you kindly give me a little information upon the following? (1) I photographed a man in May, 1900, who paid for his sitting. In September, 1903, he committed a murder, and during the time he was in prison I wrote him to give me his consent to sell his pictures, which he did in November last. He was sentenced to death and hanged. A certain paper reproduced his picture, and came to me first before doing so to ask my permission, which I said they could have by paying 7s. 6d. This they refused to do, and copied same. My solicitors have offered to settle the matter by them paying two guineas and their costs, one guinea. This they refuse to do under these conditions. Do you think we have a case? (2) When a sitter is invited to sit and no payment is made by him is it necessary to register that picture to vest the copyright to the photographer, unless he is going to take action, and then it must be registered? Is this so?" In reply: (1) If you had not registered the copyright before the paper reproduced the portrait you have no remedy. Have not your solicitors told you that? (2) No damages or penalties can be recovered for anything done prior to the registration of a picture. Write only on one side of the paper in future.

MESSRS. Newton and Co., of 3, Fleet Street, E.C., have just received a large series of negatives of the Trans-Siberian Railway including Port Arthur, Vladivostock, Lake Baikal, groups in Manchuria, etc., which they are publishing as lantern slides; also a series of Corea and the disturbances in the Far East.

SOUTH DEVON Teacher's Camera Club, at its annual meeting last week, at Newton Abbot, re-elected Messrs. A. W. Searley and Mole president and secretary respectively. It was decided to commence the New Year's programme on March 26th, when the president will deal with "The Laws of Composition as Applied to Photography." Demonstrations will be given during the season on platinotype work, enlargement, and the carbon process, and a meeting will be held for criticism of negatives and prints. During the summer Newton, Ivybridge, Bishopsteignton, Ashburton, Buckfastleigh, Babbacombe, and Torquay will be visited.

LIVERPOOL Amateur Photographic Association.—At the last week meeting, Mr. Gilbert Y. Tickle led the subject on "Common Objects of the Seashore or Seaside Snapshots." A large number of slides belonging to about a score of members were passed through a lantern dealing with the subject, and comprised both interesting and amusing series, notable among the latter being Mr. Dibdin's studies. The lecturette given by Mr. Saxby, dealing with "specimens" found in Barbadoes earth, was given in a very masterly manner, and the microscopic slides taken by him from examples arranged by Mr. Norman Thomas reflected great credit on both photographer and the arranger alike.

The annual meeting of the Royal Astronomical Society was held last week at Burlington House, among those present being Mr. Choate, the United States Ambassador, who attended to receive the Society's gold medal for presentation to Professor G. E. Hale for his method of photographing the solar surface and for other astronomical work. Professor H. H. Turner presided and, in awarding the medal, said that he would refer to the words of Professor H. himself—namely, that "the sun is the only star whose phenomena can be studied in detail." They would all assent at once, not only to the proposition itself, but to the obvious corollary that particular attention should be paid to solar phenomena. Far too little attention had been paid to the sun hitherto. It was a happy augury for a new century that they were able so early in its course to confer well-deserved honour upon one of those who were taking the lead in rectifying the omissions of the past. Having paid a tribute to Professor Hale's work, the chairman went on to say that it was a great disappointment to them that Professor Hale could not be there personally to receive the medal, but having been led to pay a visit to California, to study the conditions for solar work, he had found this so admirable that he felt compelled to begin operations there without delay. Mr. Choate, in receiving the medal, said that he considered it a great honour to be asked to attend, and to receive the medal. He would have much pleasure in transmitting it to Professor Hale. It was a medal, the awarding of which was the crowning honour of any astronomer's work in the world. American astronomers enjoyed unusual facilities for prosecuting their work. They had 300 clear days and nights out of 365, and with all the facilities they certainly ought to do something. Public and private munificence, too, contributed very largely to their opportunities.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Scottish National Exhibition.
The exhibition promoted by the Scottish Photographic Federation, now open in the Sandeman Art Gallery in Perth, is an innovation in Scottish photography. It is a selected exhibition of the best Scottish work (distinctly from Scottish workers), and the fact that little over pictures are hung from some 400 submitted to the selection Committee shows that the committee have done their work in no half-hearted spirit. If an exhibition is to be run on these lines the selection must be strict, as every picture has, as it were, the hallmark of the committee that it possesses real merit. That the scheme has the approval of the leaders of Scottish photography is evidenced by the presence of their pictures on the walls. We are glad to notice that the committee has not entirely neglected the technical side of the art, as shown by the presence of some micro-photographs and Nature studies. This theme might, we think, be more developed in future exhibitions; photography has other sides than the pictorial, and it behoves a national body to pay attention to them.) The work of the Federation during the first year of its existence, culminating in this exhibition, is worthy of all praise, and clearly indicates that the country was ripe for such an institution.

As will be seen by our report on another page the Camera Club members were busy last week in consideration of several questions concerning Mars—

not the god of war—we have enough of him just now in the daily newspapers—but the planet called after his name. There was an unusually long discussion after the lecture, but one very amazing point concerning the history of Mars was not touched upon, and yet it is worthy of record as a curiosity of literature. Until the year 1617 Mars was believed to be destitute of any moons or satellites, and if we refer to the entrancing works of Procter, or of any other astronomers up to that date we shall naturally find no record of them. They were discovered by Professor Asaph Hall at Washington in the year named. But if we turn to "Gulliver's Travels" written very nearly two hundred years ago we can find in the "Voyage to Laputa" these remarkable words, "They have likewise discovered two lesser stars or satellites which revolve about Mars." It is a remarkable thing how many discoveries have been foreshadowed in the irresponsible pages of fiction. Most photographers are aware of the manner in which picture-making by the aid of the sun is described in one of La Fontaine's fables in the seventeenth century. Other writers of even older date have described an apparatus very similar to the electric telegraph. But this forestalling of the astronomers with the satellites of Mars is more definite and complete than anything else of the same kind. Doubts arise, indeed, whether Dean Swift should not be credited with the first recognition of the two small attendant planets of Phobos and Decimos. It was a happy prophecy anyway!

War Pictures.

The illustrated Press of the present day by its enterprise conveys to us at home a very good idea of what occurs at seats of war, however far distant they may be, whether we are personally concerned in them or not. We learn that Mr. Frederic Villiers, who has been through several campaigns as an artist, is starting for the seat of war in the Far East; also that Mr. Melton Prior is already there with the Japanese. Mr. Prior is, as usual, commissioned by the "Illustrated News." This gentleman is always accompanied by his camera, of which he is making large use on the scene of battle. The American illustrated Press is not behind the English in the matter of war pictures, and we learn that Mr. James H. Hare (son of Mr. George Hare, the well known camera maker), who for some years past has been located in the States, is on his way to the seat of war with his camera. He represented "Collier's Weekly" at the American-Cuban war. Photographs of war episodes convey, of course, a more reliable idea of the events than do hand-made sketches. Photographs at seats of war are not such a modern event as some seem to imagine. The late Mr. Roger Fenton, with his camera, went to the Crimean war, and produced some excellent pictures. At that time there were no rapid dry plates as now, and he had perforce to

work the wet collodion process, preparing his plates and developing them on the spot. Some negatives, however, we believe, were by the waxed paper process. Fenton's negatives, we are told, were all 12 by 10, or larger, so that it will be seen that his difficulties were infinitely greater than those of the modern war photographer. Still, he managed to surmount them, and brought home a series of good, as well as interesting, pictures.

* * *

The Tele-phonoscope.

This is the name which we have ourselves invented, and we feel rather proud of it, for an appliance which several people seem to have invented or are trying to invent. The people who have invented it, or say they have, have failed, and we look to those who are, to use a colloquialism, still "on the job." According to a telegram "from our own correspondent," which appears in one of the papers, no less a personage than Mr. Thomas A. Edison is one of these latter. He has "announced that he hoped shortly to perfect a camera obscura attachment to ordinary telephones which would permit users to see each other as they conversed." We are further told that the great American inventor has been at work on this instrument for a number of years, during which time success has again and again seemed to be within his grasp, but that unexpected difficulties have occurred. It is impossible to say what amount of truth there is in this telegram, for it has long been the custom with American journalists to saddle Edison with all kinds of intentions of which he is really quite innocent. He is a practical man, and no one doubts his genius, and, being so gifted, he is not in the habit of devoting his valuable time to an invention the utility of which is extremely doubtful. We are very uncertain of the advantage of being able to see telephonic correspondents as we converse with them, and we can imagine that under certain circumstances such recognition would be a positive hindrance to business. In the case, for example, of a pretty girl being established at the exchange we can foresee the possibility of clerks in the various surrounding offices ringing her up continually on the veriest pretexts just in order to beguile the monotony of their daily duties by a vision of her sweet face. And it would be necessary to replace all the well-favoured girls at the exchange by metal less attractive. What really would be valuable would be a simple attachment to an ordinary telephone of some kind of recording apparatus, and even this would be useless as evidence in a court of law unless it comprised something equivalent to a signature, so that it could be identified with one particular person and no one else. It is easy enough to distinguish the peculiarities of a correspondent's voice in the telephone, but at present we know of no means of describing them graphically.

Phosphorescence of Plates.

The communications to "Nature" on this subject still continue; last week one from Mr. Walter J. Clarke reduces the problem to its simplest dimensions, and indicates an experiment which can be carried out by anyone without need for any experimental outfit. After quoting several experimenters' results he writes:—"May I point out that the phosphorescence is exhibited by the mixed pyro and soda solutions in an ordinary white developing dish without any contact whatever with any photographic plate or paper, and without adding any other salt; but the phosphorescence is not so brilliant, and takes a longer time before it can be seen. The phosphorescence is distinctly seen by pouring the solution of pyro and soda in the dish, allowing it to remain a few minutes, and pouring it away so that only a few drops are left in the dish. I tried to obtain a photo-

graph of an object between the luminous disc and the camera, but without success." Here is, as we say, such a simple experiment that anyone may make it for himself, and we determined to ascertain how it would work in our hands. Placing in separate vessels the soda and pyro solutions which needed only to be mixed to be ready for developing, we entirely shut off light of any kind, after laying at hand a perfectly clean white porcelain dish. We then mixed the solutions, and kept them in the measuring glass for several minutes, giving a gentle shake at intervals. Result—nothing visible. We then poured the contents of the glass into the white dish, and drained them back into the measure. Still nothing to be seen. After waiting a couple of minutes, we emptied the developer back again into the measure, and poured it backwards and forwards several times over, but failed to obtain any visible result. In the face of so much written testimony of the production of phosphorescence it would be carrying scepticism too far to doubt the existence of this lighting up of the plate, yet we should be inclined to suggest, with the writer quoted in later note with regard to Blondlot's N-rays, that this phosphorescence is due to "radiations to which some men are blind and others not so," and that the precise condition upon which the effect depends yet remain to be discovered. We may narrate an incident of what occurred during the progress of our experiment, but which we should not like to suggest as an explanation of the results obtained by the experimenters we have referred to. On one of the occasions when we were draining the dish into the measuring-glass we were startled by a distinct luminosity of the plate, while the effect we were able to repeat. Its cause, however, was in no way abnormal; it was merely the reflection caused by the temporary brilliance imparted to the glowing end of a cigarette!

Registration in Double Printing.

Various devices have from time to time been introduced for securing accurate registration when the picture has to be made as a combination print from two or more negatives. Many different forms of registering frames have been introduced by the use of which the print may be removed at any stage of the printing and replaced again in perfect register, the latest form of which was that shown by Mr. Nelson J. Cherill at a recent meeting of the Camera Club, and which was described in our issue of the 12th inst. With this frame the printing may be arrested at any stage and one or more thicknesses of celluloid or other media introduced between the negative and print and the printing complete, accurate registration being ensured. A method of double printing has more than once been described in these pages by which the print, during the printing, may be removed from the frame and replaced on the negatives in perfect register. That method does not require any special frame as any ordinary one will answer. The plan has been used for the production of the so-called "Denier effects." This "dodge" does not at present seem so well known as it deserves to be, we will again describe it for the benefit of some of our younger readers. For the printing frame one of what is now known as the "box form" is preferable, though one of the usual type may be utilised if it be fitted with a glass plate. The glass, whichever form be used, must be securely fixed in the rabbet of the frame so that it cannot shift. The negative is then fastened in position to the glass with strips of gum paper, or, better still, with strips of American sticking-plaster. This is no trouble, remove from the negative or the glass, and may be used over and over again, whereas the gum paper is troublesome to get off. Next we take a piece of cardboard, somewhat larger than the picture to be produced, and it must be cut to a right angle at one end. Any photographic mount w

answer, as they are always truly cut. To this the sensitive paper, or carbon tissue, is attached by two or three small touches of thick indiarubber solution. In placing on the negative the cardboard must be pressed up closely in one angle of the frame, and perhaps the most convenient corner is the top left-hand one. Now, it will be seen that the card and print can be removed from the frame and replaced on the negative in accurate register as many times as may be required provided the cardboard is pressed closely in the angle of the frame. If the frame has a hinged back the printing may be watched in the ordinary way, and only be removed when it is desired to intervene the mask, celluloid, or what not. Very excellent Denier effects may be obtained by partially printing in contact with the negative and then interposing a sheet of celluloid, then another, or perhaps a third, before the printing is finished. Sometimes the printing is commenced through the celluloid and finished in contact with the negative. Each way, to an extent, gives a different effect. Some have suggested commencing the printing with the paper in contact with the negatives and finishing with it in contact, the intermediate printing being done through the intervening media or, maybe, mask. This system of securing registration in different printings was that utilised by M. Lambert when he was demonstrating his Lambertype carbon process in this country some thirty or so years ago.

Photography and Physiology.

The connection between photographic action and physiological phenomena has been exploited in many directions of late, some of them being very remarkable. We are reminded by recent accounts of work done, or mapped out for the future, of the particular behaviour of one special photographic chemical, nitrate of silver, when used in connection with human physiological processes. This chemical has important uses as a medicine, and is given in small daily doses made up in the form of a pill in certain severe forms of disease. Its action is sometimes remarkably effectual; but it is a medicine that should only be employed as a last resource, for the patient too often becomes a walking piece of sensitised—shall we say—tissue. The face and hands, probably through the action of light upon the absorbed nitrate of silver, become livid and corpse-like, and present a perpetual appearance something like the temporary hideousness of one illuminated by a monochromatic light like sodium, or resembling that of people illuminated by the Cooper-Hewitt mercury lamp. Here is an example of light action, painful to contemplate, brought about by artificial means. Much has been written lately of light action in an opposite, a benignant direction. Briefly put, it is stated that a sufferer from small-pox if during the whole of his illness he be kept in what may be termed a continuous dark-room light—one where nothing but red light gains entrance—passes through a milder attack, and recovers without the disfiguring “pitting” of the features, one of the loathsome sequelæ of this disease. Photographers and those engaged in the preparation and use of sensitive photographic products have long been familiar with the fact that to dark-room rays are ascribed certain properties which experience has failed to confirm; for example, quite early in the eighties, a mild scare was created as to the alleged harmful effect which the light in dry-plate coating-rooms, developing-rooms, etc., had upon the eyes, and even now it is frequently suggested that some sort of action is caused by these rays on the skin. The whole thing, however, like the interesting maternity experiment of Dr. Hill, to which we referred a fortnight ago, is, we fear, more in the nature of a spectral myth. We live in times when light in its various forms of manifestation or energy excites a remarkable degree of interest. Scarcely a week

passes without the newspaper columns are filled with interesting statements as to the effects which the innumerable rays now, so to speak, “on the market,” are supposed to have on organic and inorganic bodies. Here still further in the latter direction we have M. Blondlot and his N-rays, radiations from certain structural portions of living beings, which possess properties analogous in some respects to Röntgen rays, capable of exciting phosphorescence, and so on. His opinions and proofs are treated with the respect due to the utterances of men of scientific eminence; but, hitherto, no one else has been able to obtain similar results. He himself has explained and described his experiments to the Paris Academy of Sciences, and has shown how the radiation is separable into eight bundles, whose respective indices vary 1.04 to 1.85. He has also determined the wave lengths of these separate constituents. But, so late as the current number of “Nature,” we have a letter from Mr. J. B. Burke giving in detail the result of his unsuccessful endeavours to repeat M. Blondlot’s experiments. He is at a loss to discover any other explanation than that M. Blondlot has come across “radiations to which some men are blind and others not so, and that the precise conditions upon which the effect depends yet remain to be discovered.”

* * *

Rustic Photography.

We may suppose that every photographer who has in his nature one spark of poetic feeling, must have wished at some time or other to work out by means of the camera some story after the manner, say, of Hogarth. Every picture lover knows his “Rake’s Progress,” his “Marriage à la Mode,” “The Industrious and the Idle Apprentice,” etc. Of course the photographer must come a long way after Hogarth, and to produce picture stories of this kind, he would require as models, actors and actresses of transcendent powers, and a stage manager of marvellous ability to pose them—well-nigh impossible conditions to fulfil. But, if the photographer will content himself with the illustration of some well known poem, which deals with a particular phase of human life—rather than with the movements of a few actors in a life drama, he does not set himself an impossible task. Let us take as an example of what we mean that deservedly famous example of word painting, Gray’s “Elegy in a Country Churchyard.” The photographer need not be tied to that particular churchyard at Stoke Pogis where Gray imagined this masterpiece. He can choose any “God’s acre” which by its picturesque quiet may commend itself to him, and then, if it in him lies, he will find a subject for illustration in almost every stanza of the work. To quote only two lines—

The lowing herd winds slowly o’er the lea,

The ploughman homeward plods his weary way.

Perhaps we should have written in the past tense and said those illustrations for this poem might once have been found ready to the hand of the photographer. For rustic ways have undergone a marvellous change since Gray was in the flesh—nearly a century and a half ago. And this change has come upon the face of the country within the last three decades. During this short time the picturesque features of country life have all but disappeared, and supposing that we had among us a poet of Gray’s calibre, he would have to go far afield to find anything which would tempt his muse. The steam plough with its heavy snorts would certainly not appeal to him, nor would the noisy thrashing machine, whose hum is far louder and not in any way of a soothing nature of the hum of a bee. Then there is the reaping machine, which has taken the place of the man with the scythe. In a word the old English farm with its sleepy ways, and its quiet beauty, is being elbowed out by steam and electricity, and

pastoral poetry is going out with it. The last shred of rustic simplicity is torn asunder with the recent introduction of an electrical milking device. "The pretty girl milking her cow" is no longer to find a place in farming life. She is now superseded by a mechanical contrivance which is called "The Lawrence-Kennedy cow milker." There is a picture of it in the "Illustrated London News" from which we gather that the machine is quite automatic in action, and that placed between a couple of animals as they stand at the byre, it will operate upon them in the most efficacious manner. It seems to consist of a receptacle for the milk in which a vacuum is created, and this is connected by flexible tubing with the cows. Then there is a thing called a "pulsator," which we read can be so regulated by screws to give "adjustability to the characteristics of each cow." What an awful revulsion of feeling there is when we turn from Gray's line—

Along the cool, sequester'd vale of life,

and read about adjusting machinery to the peculiarities of each cow. If this kind of thing does not "implore the passing tribute of a sigh" we know not what does. But we have said enough to show that if an enterprising camera bearer wants to pourtray the essential features of English rustic life as seen by Gray and contemporary poets he must not seek them in England, unless he can find some "sequester'd vale" where mechanical abominations are as yet unknown.

INTERNAL REFLECTION IN CAMERAS.

HOWEVER carefully the photographer may exclude every stray ray of actinic light from his plates until they finally emerge from the fixing bath, there still remains a certain liability of his efforts being frustrated in a way that is difficult to prevent. We refer to internal reflection in the camera during exposure. This is of far more frequent occurrence than might be imagined, and a consideration of the subject is not without interest.

A very good idea of the manner in which light may be thrown back from the bellows lining can be obtained by making the following simple experiment, in which we exaggerate the conditions to render the effect more visible. The camera is pointed up and focussed on a bright light, say an incandescent gas burner, until the flame can be seen sharply defined on the lower margin of the screen. We shall then notice, about an inch above the image, a marked patch of bright, reflected light. If we remove the focusing screen and look into the camera the cause is immediately apparent; the topmost rays entering the lens are striking sharply on the inclined surface of the bellows, and are thrown back in full force on the screen (see Fig. 1).

FIG. 1.

This phenomenon is sometimes wrongly ascribed to "getting the light in the lens," which is quite a different thing, though both are largely amenable to the same remedy—the use of a sky-shade. This experiment affords an effective illustration of what may easily happen in photographing interiors where a brightly-lit window comes near the edge of the plate, or in landscape work, where the sky occupies a similar position over a comparatively dark subject. Much of what is put down to halation by the unsuspicious worker is really internal reflection of this kind, and might be avoided either by screening the lens or altering the position of the camera.

The conical bellows is a frequent distributor of stray light. The old-time photographer, with his sliding body instrument, was in this respect better off than some of his modern successors. Internal reflection was practically unknown to him, and not a little of the splendid clearness and vigour noticeable in negatives and positives of that period was due to this fact. Our predecessors, too, seldom took it into their heads to employ a lens of greater covering power than was really needed, more commonly erring in the other direction. The reflection often caused by using a lens of unnecessary covering power is illustrated by Fig. 2,

FIG. 2.

which shows how the rays which would otherwise go to form a larger image, as indicated by the dotted lines outside the camera, are stopped by the ridges of the bellows and reflected on to the plate. It does not seem to be generally known that this kind of reflection may be prevented by the use of a suitable circular hood on the front of the lens to reduce the angle of view.

It is evident that the material employed for the bellows lining is a question of some importance. As a rule, there is nothing to complain of in this respect, but occasionally we come across cameras where some kind of linen has been used of a distinctly shiny character. We can only advise the possessors of such to coat the interior of their bellows with a dull, black varnish, since they can hardly expect to obtain perfect negatives under the preceding conditions. It was once suggested by a worker that a red cloth might be more suitable than black, for the somewhat curious reason alleged, that the dyes used for the latter were said to be of a shinier nature than the red dyes. Be this as it may, a series of trials instituted for the purpose showed conclusively that there was far more reflection from the red than the black, as, indeed, might have been expected.

From what we have said, it would appear that the square bellows camera possesses certain advantages, although, of course, the conical form is perfectly satisfactory where care is taken to avoid the conditions giving rise to reflection.

Theoretically, the ideal course would be to have our camera of a larger size than the plate we intend to use, but retaining the smaller lens. There is then no possibility of reflection, as will be seen by Fig. 3. Considerations of

FIG. 3

weight and bulk are fatally against this proceeding for ordinary use, but the idea is worthy of attention in the case of apparatus for scientific purposes.

Space will not permit anything to be said of other forms of internal reflection, such as that from an imperfectly-blackened lens mount or the so-called "ghost image" thrown from the inner surface of the front combination of a badly-adjusted rectilinear lens. They are, at all events, less likely to occur, and more easily perceived and remedied, than the trouble we have been discussing.

In all cases it is more particularly when the apparatus is tilted that there is a probability of internal reflection, as will be readily understood. The photographer will find himself repaid by removing the screen and carefully inspecting the inside of the camera before making an exposure. He will often in this way be able to detect and prevent the evil, which otherwise would have passed unnoticed. It must be remembered that the reflection consists more of a general diffusion of light over the plate than of a special illumination of one portion, and so only makes its presence evident, in most instances, by a flatness and lack of brilliancy in the resulting negative.

At the Röntgen Society's ordinary general meeting on Thursday, March 3rd, 1904, at 20, Hanover Square, the presidential address will be on the subject of "Some Laboratory Notes of the last Six Months."

The Mysterious Poisonings at Sheffield.—The mystery attending the poisoning of John James, labourer, and the narrow escape of several women, at Sheffield, has been solved. At the inquest held on Wednesday last week, Police-Inspector Hebb stated that, next to the house occupied by James was a Siemens' blast furnace, which had been shut down since last September until the Thursday before the fatality. Dr. Carter, police surgeon, who had made the post mortem, said the cause of death, he had no doubt, was poisoning by carbon monoxide gas. This gas was the ordinary product in large quantities of the Siemens' steel process, and was not a constituent of bad sewer gas. Dr. Scurfield, Medical Officer of Health for Sheffield, described his examination of the house and the surrounding court. He agreed with Dr. Carter as to the cause of death, and also as to the source of the gas. The cellar of the house runs up to the footpath, and occupies the archway next to the works in which the Siemens' process was carried on. He found no leakage of coal gas, but the source of the monoxide gas could not be determined until the ground around the house and in the works had been opened out. It was possible that the gas had been absorbed in the earth through a flue which leaked. A verdict was returned that death resulted from poisoning by monoxide gas, but expressing no opinion as to the source whence it came.

PHOTOGRAPHIC LENS MAKING.

[A lecture delivered before the Photographic Society of Philadelphia.]

THERE is probably no other branch of organised manufacture which demands such precision of workmanship as is necessary for the production of the best photographic lenses. The bricklayer and the tailor are proud of working within an eighth of an inch, the cabinet-maker of working to a hundredth, the machinist deals in thousandths, the watchmaker in ten-thousandths; but the photographic lens maker works in hundred-thousandths of the inch every day until he forgets the remarkable character of this performance, for it becomes instinctive.

Before proceeding to describe the making of lenses, it may be well to speak of the tools and appliances necessary for the work, and to say that owing to the special character and extent of the lens-making industry, suitable machinery and tools cannot be purchased ready developed, as looms for weaving may be bought; but opticians have either to content themselves with comparatively crude appliances, or to design and make more perfect ones for themselves.

The glass of which lenses are made is purchased in the form of rough plates from Continental and English makers. This is expensive material, a plate four inches square costing sometimes as much as twelve dollars. The uniform practice at Leicester is to grind and polish both faces of these raw plates to facilitate thorough inspection of the material before being made into lenses. In the course of this examination a large proportion of the glass is marked to be cut out and thrown away. It might well be thought that a material so expensive should be free from all defects. But many of the difficulties of manufacture are serious and inevitable. In order that the various glasses shall possess the necessary refractive and dispersive powers, a large variety of materials is employed by the makers to modify or temper the fusible earths which form the chief constituents of the glass. The perfect incorporation of these materials by melting and stirring them in a crucible, and the avoidance of discoloration and dirt, are highly delicate tasks.

When by these means the optical glass maker has prepared a mass of glass, it is allowed to cool and then broken into fragments. Of these only the cleanest and most perfect are selected for remelting to make the final cast. But in melting a peculiar difficulty is experienced. As the pieces fuse together bubbles of air become imprisoned in the vitreous mass, and only the largest of these quickly rise to the surface and escape. The smallest bubbles remain suspended, and can be removed only by patiently waiting until their feeble force carries them to the surface. But in the course of waiting more serious harm frequently arises. For the same force of gravity which expels the bubbles works other changes within the body of the glass. Its heavy constituents sink, and the resulting lack of homogeneity, although invisible to the eye, is far more hurtful to the action of a lens than is the presence of tiny bubbles, which do not of themselves affect the defining power of the lens in the slightest degree. Like the uncut leaves of a book, which are a guarantee of the book being new or unused, bubbles in certain optical glasses are proof that the glass has not been spoiled by long-continued heating, and the really wise accept a moderate number as the inevitable accompaniment and mark of good quality. When, however, the glass plate is formed and set aside to cool a new difficulty arises, for in its small way it behaves exactly as the earth does under similar circumstances. Originally hot and molten, like the glass, the earth has for long ages been radiating its heat outwardly into space, and its crust has already cooled and formed itself into the rigid rocks with which we are familiar. But the interior of the mass is yet hot, though slowly cooling. As it cools it shrinks, and, like the kernel of a nut, in shrinking, it pulls and tries to part from its shell. In its small way the cooling slab of glass behaves precisely in this manner. Its outer crust first becomes

rigid, and the subsequent cooling and shrinkage of the interior sets up an inwardly pulling strain whose visible, and therefore least objectionable, effect arises when it is sufficiently severe to crack the glass. When the internal strains formed in this way do not result in cracking the material, the glass is still unfit for the production of lenses, although the defect is not outwardly visible. Accordingly, in the process of manufacture, after the glass has been fused into the form of a plate or disc, it is put red-hot into a specially-constructed oven, where it is slowly cooled through a period of several weeks, so that at all times its temperature is as nearly as possible equal throughout the mass. In this way it sets and becomes rigid, first at its outer surfaces; internal strains are thus as far as possible avoided. By the use of a special instrument any particles of dirt, and veins or bubbles, are made visible, and such defective portions of the plates are cut off and thrown away. The use of polarised light, familiar to microscopists, enables any internal strains such as have been described to be detected, and material faulty in this respect is also discarded. By the time these processes have been carried out the raw material, expensive in its first state, has become still more valuable, and is now ready for being made into lenses. In speaking hereafter of the method of shaping lenses, the term "lens" will be applied to the simple lens or part composed of one piece of glass, several of which are combined to form the complete instrument. Unlike wood or metal, glass is a material which cannot be cut in the ordinary sense of the term "cutting." Glass is so brittle that only two ways are available for shaping it. One is to heat it until it becomes plastic, when it may be pressed or cut into shape; and the other is to take a piece of glass of sufficient size, and, without heating, to break or rub away its superfluous parts. Cheap lenses are sometimes made by the former method, which is much the less expensive, but the process frequently results in those internal strains which have been mentioned, and in other defects which make it unsuitable for first-class lens-making.

The best lenses are shaped by taking pieces of selected glass of sufficient size, and breaking or rubbing away their superfluous parts; and all the processes to be described for making lenses of glass, even to the final act of polishing, are essentially of this character. If the lens to be made is a large one, an entire slab or disc of glass may be necessary for the purpose; but for ordinary lenses, such as are used in hand cameras, one plate of glass may be sufficiently large for a number of lenses, and so thick that it has to be cut into slices. This is done by sawing it, the saw being a rotating metal disc with tiny diamond points fixed in its rim. The glass is presented to the saw, which slowly and steadily makes its way through the glass, dividing it into slices of sufficient thickness for the lenses being made. From these pieces circular discs are made, and then begin the processes for shaping their surfaces to the spherical forms which give them their peculiar power as lenses. To effect this a revolving spindle has attached to it a metal tool which is shaped to a spherical form, either convex or concave, the counterpart of the curve it is desired to produce on the lens. Such a tool being rotated, and supplied with coarsely-powdered abrasive, as emery or carborundum, and with water to keep everything cool, will grind to shape the surface of the piece of glass, which is applied to it by hand. At first sight it might be thought that the soft metal tool and not the hard glass would suffer most in this process, but it is not so. The hard particles of abrasive become pressed and embedded in the surface of the metal, each little particle scraping up for itself a tiny metal buttress which holds it and compels it to do its work in scratching the glass. It is by grinding in this way that the glasses are first roughly shaped; and the succeeding processes, up to the final polishing of the lens, consist in skilfully rubbing with a series of tools more and more accurately formed, and with abrasives more and more finely powdered. For

all the earlier stages emery is the abrasive, and for applying emeries carefully graded very accurate grinding tools are necessary. These are made in pairs, one convex and the other concave, the two being ground together until their curvature is not only of the right radial measurement, but so perfectly spherical that the tools touch all over their working surfaces, in any position of contact, and when any pair is put together, clean and dry, and the upper tool lifted, the vacuum between their surfaces will raise the lower tool although it may be many pounds in weight.

For the many curves which are ground, large numbers of these expensive tools are required, varying in size and curvature from that of the smallest marble to curves whose radius is measured in inches, feet, and upwards. With these tools, and various grades of emery, the surface of the glass is gradually changed from the coarsely-ground condition in which it was when first roughly shaped into one free from scratches, and commencing to show signs of polish. Meantime the axial thickness of the lens has been measured by means of a little instrument, which indicates the thickness on a dial, and enables the workman to secure minute accuracy of measurement. At this stage of grinding the roughness of the glass, although apparent to the eye, is exceedingly small in absolute measure, being comparable with the length of a wave of light; and the succeeding process of polishing consists in rubbing down these very minute prominences to one general level by a further process of abrasion. For this purpose even the finest emery is not sufficiently fine, nor can metal tools be used, because a hard surface coming in close contact with the glass would scratch it. The abrasives used for polishing glass are various earths and metallic oxides, such as tripoli, rouge, and putty powder (oxide of tin), and these are applied with water upon rubbers made of some soft substance. Where cheap lenses are made the rubbers are frequently elastic materials, such as paper or cloth, which act quickly, but have the disadvantage of destroying the perfect spherical form of the lens by over-rubbing its outer margins and rounding them. For polishing the best lenses such elastic materials cannot be used, the lenses being polished with rubbers made of waxes or resins, which, although soft, so that they will not scratch the glass, are inelastic, and cannot, if properly applied, distort the curvature of the lens. These wax polishers are held in supporting shells of metal. The operation of polishing lenses demands exceptional skill, and although much ingenuity has been spent in designing machinery for the purpose, much of the work is best done by hand. In hand polishing the glass is fastened with pitch to a suitable handle, and the polishing tool is rotated on a spindle. The rotating tool is slightly coated with the moistened abrasive; the lens is held against it so that their spherical surfaces are in contact, and the operator, with a rapid and delicate motion of the hand, which can only be properly acquired by experience, rubs the surfaces together, changing continually the position of the lens, and securing the equal polishing of the whole surface. At intervals during the process the work and the tool are cleaned, and fresh abrasives applied to continue the process until it is complete. At each interval the lens is carefully examined, and as it approaches completion the accurate formation of its surface is tested by means of what is called a contact gauge. This gauge consists of a piece of very hard glass, having on it a spherical surface very accurately ground and polished, an exact counterpart of the surface it is required to test. When the gauge and the lens to be tested are very carefully wiped, placed together, and viewed by reflected light, brilliant colours are seen, formed by "interference" at the two contact surfaces, colours which exactly resemble those seen in soap bubbles. These colours can only be produced when the two surfaces which form them are exceedingly close together. They have their maximum brilliance when the surfaces are a few millionths of an inch apart, and if the separation of the surfaces varies

in a soap bubble it varies with the thickness of the film) colours change and spectrum bands are formed. It is by varying the brilliance, the form, and the separation of these bands of colour that the lens-maker is able to measure and to work with that degree of precision which is unsurpassed in any other branch of industry. When the workman has finished a batch of lenses they are passed to the lens-testing room, where they are again examined, and, if passed as perfect, are given into stock, to await the arrival of their metal settings, and are then being assembled and adjusted as complex lenses.

The accuracy in the metal work of a lens is first of all essential to the perfect performance of the instrument. But it has other elements of value. One is found especially in the case of flanges and flange screws, which must be accurately made if they are to be usefully interchangeable. The majority of the parts of a lens mount are in the form of rings, which are first roughly shaped by casting, or they are made from the metal tubing or sheet. Such pieces are accurately shaped by turning them in the lathe with various cutting tools which form upon them their shoulders, shoulders, recesses, or other necessary details. To secure the prescribed accuracy of measurement the workman is furnished with gauges for each essential detail, and in working out these precautions unusual in mechanical work have been taken. For example, there is the difficulty of temperature and expansion to be met. When a piece of metal is turned in the lathe, heating as it does at the rate of several hundred feet a minute, it becomes heated by the action of the cutting tools, and when cooled and thus expanded is, of course, not in a fit condition to be measured with a cold gauge. To meet this difficulty, compressed air is blown upon the work to keep it cool. Even with this and other precautions it is found difficult to shape lenses by means of cutting tools alone, within limits of error less than one-thousandth of an inch. And although these variations are really small compared with those which are commonly to be found in good instrument work, there are parts of lens mounts, especially those subject to wear, in which the practice has been adopted of securing still greater accuracy, while hardening their surfaces, by subjecting them to heavy pressure in finely-finished hard steel dies.

The polishing of brass work is more or less familiar to most people. The fluting of the rims of cells, a marking like that which is found in the periphery of silver coins, is produced in the lathe by rotating the piece and impressing it with a steel tool having the requisite pattern cut in its rim. The lacquer which is used to protect the metal work from the tarnishing action of the atmosphere is composed of shellac dissolved in alcohol. The lacquer is applied with a brush, the work having previously been heated sufficiently to evaporate the solvent as the lacquer is applied. The shellac is thus distributed evenly over the surface, and becomes hard when the metal is cooled. It will be seen that mounts should not afterwards be unnecessarily warmed or the lacquer may be softened and damaged; nor should they be washed with alcohol, as is sometimes advised, because alcohol will remove the shellac. After lacquering of the parts is finished, the scales for iris diaphragms, distances for focussing, and all other descriptions are usually found on a lens, are engraved upon the mount by a machine which is really a development of the well-known pantograph.

The action of a photographic lens in forming an image is simply to receive light from each point of the object, and to send the light to corresponding points which form the image, and the capacity of a lens for producing fine definition depends simply upon its power to condense, very accurately to a point, the light which it receives from any other point. Accordingly, in testing lenses, instead of merely putting a lens in a camera, focussing an image, and attempting to judge whether the image is sharp or not, the lens is first put into an instrument, at the end of which, furthest from the operator,

is a small flame or source of light, bounded by a pin-hole. The light passing through the pin-hole spreads out in conical form until it reaches a condensing lens, called a collimator, which bends the light rays perfectly parallel, so that they behave as if they had come from an infinite distance. In the path of these parallel rays, and near the operator's left hand, the lens to be tested is supported, and the light which it thus receives is condensed to a point which he examines by the aid of a microscope. By examining this point of light, and moving the lens so that the light passes through it in various directions, he is able to tell a great deal more about its defining power than could be told merely by taking photographs with it. Sir Wm. Abney has said that the barrier to finer definition in photography lies not so much in the lens, which is now perhaps as perfect as anything can be, but in coarseness of structure of the modern sensitive film. It is well known to opticians that this is the case; but they know equally well that it is not alone the structure of films which limits the definition in ordinary photographs. Where most photographers fail in getting the utmost possible duty from their lenses is in the imperfect setting of the film in the true plane of the image. And this failure is due not so much to want of care or of knowledge on their part as to the loose, elastic, and inaccurate construction of the average camera. So, finally, having endeavoured to show something of the elaborate care which is used in making good lenses, let us leave with you one other thought: the need of corresponding care in using them aright.

J. RONALD TAYLOR.

MESSRS. W. AND D. DOWNEY had the honour of photographing the Princess of Wales on Monday morning.

The Hydroscope and its Success.—Cavaliere Pino is the inventor of a machine called the hydroscope, to which reference has already been made in these columns. The instrument consists of a long tube carrying an optical instrument at the end. Objects at the bottom of the sea are reflected upward, where they may be readily studied from the deck of a steamer. By means of the hydroscope, Pino succeeded in bringing up objects from the sea that have been concealed for two thousand years. These were found off the Grecian coast, and include some valuable art objects—creations of ancient Greek art.—*The Scientific American.*

An Oxyacetylene Blow-Pipe.—An oxyacetylene blow-pipe is described by M. Fouché in the Bulletin of the French Physical Society. The flame is formed by the combustion of a mixture of one part of acetylene to $\frac{1}{4}$ of oxygen, and in order that the explosion may not travel back into the blow-pipe, a jet velocity is required, due to the pressure of a water column four meters in height. The flame melts most metals readily; it will solder iron and steel. Even silica and lime are melted by it. With a reduction of the proportion of oxygen, the flame becomes luminous, and on falling on lime the free carbon goes to form carbide of lime.

MESSRS. B. J. EDWARDS AND CO., LTD., Photographic Dry Plate and Film Manufacturers, Castlebar Works, Ealing Dean, London, W., are issuing the following circular to photographers and the trade:—"For the convenience of our customers we are compiling a list of those photographic dealers throughout the British Isles who stock our goods, and as this list appears likely to be of considerable value to every dealer whose name appears on it, we have pleasure in drawing your attention to the scheme with a view to giving you an opportunity of sharing its advantages, together with other dealers in photographic materials. An offer to include your name and address (or addresses) in this list is made conditionally upon your handling a stock of our goods reasonably sufficient for your local demands, but should you not have such a stock, and yet be willing to obtain same before March 31st, 1904, this will be in ample time for the purpose. The list of names, when complete, will be printed at the end of our handbook. Copies of this handbook are sent out in response to inquiries to amateur photographers all over the country, and as we intend, during the next few months, distributing some 500 or 1,000 copies per week, the value of such a list will be readily understood by every member of the trade."

THE VARIOUS AGENCIES WHICH AFFECT GELATINO-BROMIDE EMULSIONS.

For some time past writers in periodicals and magazines have been devoting considerable time and space to descriptions and experiments relating to the numerous "rays" that have recently been discovered.

These rays are accumulating in such large quantities that the whole alphabet will soon be requisitioned to provide names to distinguish one from another, as is the case with the ubiquitous motor-car. Under the circumstances we may feel relieved that one of the new brands of rays is temporarily disqualified, for the promoter has not yet proved its existence.

In many of the experiments which have been performed to demonstrate the existence of some of the recently-discovered rays, the effects of certain substances on the photographic film were the chief evidences brought forward, and the results were anything but conclusive. The experimenters could not have

and 'susceptibility' to surrounding influences is found in the finished article.

Electricity, for example, has a powerful effect on the photographic film. Those who have experimented with an X-ray are aware of the remarkable effect the electric spark has on dry-plate, when the spark is allowed to traverse the film. This illustration is given here of a spark impression taken by the writer. In this case a coil giving a 10 in. spark was used. The plate was merely held by one corner oblique between the brass knobs of the machine, and the current rapidly switched on and off again. The current could not have been turned on for more than 1-30th of a second, but the electric discharge during that time affected the whole plate, and along the direct lines of the flash an opaque deposit of silver was produced in development. This is an easy way of observing the effect of an electric discharge on a dry-plate; the only objection to this method is that the spark occasionally refuses to pass

Photograph of Electric Spark from Induction Coil. Natural Size.

been aware of the extremely sensitive nature of the emulsion, and the readiness with which it is affected by apparently slight physical changes.

In several of the experiments metals were placed in contact with the sensitive film of a dry-plate for several days, and because the form of the substance was visible when the plate was developed it was considered a decisive test for the presence of those particular rays which were under investigation.

Many other experiments of an equally exacting nature to the equilibrium of the sensitive film have been lately described, and because the plate develops some kind of an image the experimenter was able to prove to his own satisfaction the existence of certain specified rays.

All workers familiar with the operations of preparing the sensitive film are aware of the complex structure of the gelatine emulsion and the excessively delicate nature of its composition. The greatest care has to be exercised in the preparation of the emulsion of a dry-plate, and the same delicacy of structure

along the plate, and strikes a bee-line for the fingers that are holding it.

A still more striking proof of the sensitive nature of the emulsion is shown by the result of drawing the end of a smooth bone or ivory paper-knife over the surface of the plate. A piece of stout brown paper is placed over the plate and a paper-knife, or the rounded edge of a pocket-knife, drawn rapidly and heavily over the paper-covered film; if the plate is examined in the dark-room lamp no mark will be visible, but on development a dark streak appears across the plate. A reproduction of a print, from a plate with several of these pressure marks, is given on next page.

It is well known that the sensitive film is affected by a more or less prolonged contact with all sorts of metals, and as it is particularly the case in hot and thundery weather the effect is probably caused by electric or magnetic action of the metal with the silver in the film. Other substances besides metals affect the emulsion. Plates are sometimes packed with sub-

rips of paper between the edges of the plates; when the plates have been kept some time a distinct mark is often seen after development where the paper has been in contact with the film. In some cases the writer has found that the effect of the paper has been so pronounced that the portion of the film is gone beyond "correct exposure" stage, and reversal has taken place, that part of the film that has been in contact with the paper refusing to develop.

It is a well-known fact that the ink in printed paper affects dry-plates, even if the printed matter is not on the side of the paper in contact with the film.

When plates are kept for a considerable time in dark slides markings corresponding with the grain of the wood and the position of the leather hinges of the folding-shutter are often observable, although the slides may have been stored in a light-tight case.

It has been stated that if a piece of wood, with a well-defined grain, be exposed to strong sunlight for several hours, and then placed in contact with a dry-plate for a day or so, a faint image of the grain is found on the plate after development. As this seemed an interesting suggestion, and there was no prospect

Marks Produced by Drawing Paper Knife across a Dry-Plate.

carrying out the experiment in sunshine, the writer exposed a piece of wood to the light of an electric arc for one hour, but with this illuminant the results were nil.

The writer has lately been shown curious markings on several negatives that were taken on backed plates. One operator said streaks only appeared when the backing required a considerable amount of exertion to remove it, and in consequence put the markings down to electricity produced by friction on the plate. This seems quite possible, as the plate would be temporarily converted into a species of Wimshurst machine. The writer has had these backing marks appear on plates during development, but they may have been due to uneven backing.

There is one feature of the dry-plate that always seems out of keeping with its sensitive nature: the rapidity of the emulsion seems unaffected by cold or heat. Wet-plate workers seem to give longer exposures in very cold weather, but dry-plates seem as sensitive when exposed in frosty weather as they are in the hottest days of summer. J. I. Pigg, F.R.P.S.

PUBLISHERS' Exhibition.—A Publishers' Exhibition will be held at Connaught Drill Hall, Portsmouth, in connection with the Portsmouth Conference of the National Union of Teachers. The 1904 Exhibition will be held on Easter Monday, Tuesday, Wednesday, Thursday, April 4th to 7th next.

THE SCOTTISH NATIONAL PHOTOGRAPHIC SALON.

[Specially Contributed.]

THE advent of the Scottish Photographic Federation has introduced a new and a powerful factor into Scottish photography. The existence of the Federation made the Salon possible. It (the Salon) shows one or two noticeable features—it gives no awards and charges no entry fees, that principle has already obtained in other parts; it is distinctly national, i.e., confined to Scottish photographers, with the exception of the invitation section. That feature is, we think, not only novel but unique. It is questionable if any society would have undertaken to carry out an exhibition embodying these changes, but the Federation Council was in the happy position of having twenty-four societies supporting it, and calmly went on its way without fear. The success of the exhibition quite justifies these departures from use and wont. That the principles of the exhibition meet with approval is shown by the fact that the leading Scottish exhibitors have supported it.

The Sandeman Art Gallery, Perth, where the Salon was opened on the 13th, is an ideal housing; the room is entirely lighted with top light. The Salon Committee has covered the walls with canvas, divided into panels by strips of green-stained wood, while this again is topped by a frieze of Scots thistle and the Scottish lion rampant, effectively combined. This frieze and the general scheme of decoration is, we understand the work of Mr. J. W. Eadie, Vice-President of the Monklands Society, a member of the Salon Committee.

At the opening ceremony there was a large attendance of delegates from all parts of Scotland, as well as a representative gathering of the municipal and social celebrities of the Fair City. Mr. Coates, the President of the Federation, after a brief address of welcome by Lord Provost Love, declared the Salon open. He briefly recapitulated the history of the Federation, congratulated the Federated Societies on its success, and cordially invited those who had not yet joined to throw in their lot with the Federation and help on their labours for the betterment of Scottish photography and photographers. He pointed out the success that had already attended the various "facilities" that had been made available for the federated societies—the lists of judges, lecturers, demonstrators, circulating lectures and lantern slides, and the lantern slide competition with its 258 slides entered. He congratulated the associates on the magnificent exhibition which he had the honour to declare open.

Mr. G. D. Macdougald (Dundee and East of Scotland), Vice-President of the Federation, moved hearty thanks to the Salon Committee and Mr. Craigie, the librarian of the Sandeman Library, for their admirable arrangements, the result of which they now had the pleasure of witnessing.

Mr. D. Horn (Glasgow Southern), Vice-President of the Federation, moved a hearty vote of thanks to Mr. Coates, for opening the Salon, and also for his services as President of the Federation, services which were invaluable in the initiatory stages of the movement.

The hanging of the pictures has been peculiarly successful; the walls are not crowded (only 213 pictures were selected from some 400 sent in) and in the juxtaposition of the various pictures there is not a jarring note. Everyone, even those who were to some extent opposed to the Salon principle, were enthusiastic in their approval of the effect obtained. The fact that the exhibition was run on Salon lines was no doubt to a large extent responsible for the fact that the leading men in Scottish photography were represented on the walls.

The "Scotsman," the doyen of the Scottish press, in a lengthy notice, pointed out that the professional element was largely represented on the walls, and the exhibition lost nothing thereby, but at the same time the writer of that notice did not fail to point out the high quality of the work of several contributors practically unknown South of the Border.

The Council resolved that at each exhibition they would invite some distinguished worker "furth of Scotland" to send a typical exhibit of his work, so that the Scots might see what was being done elsewhere; this year the selected worker was Mr. Percy Lewis (whose phenomenal success at the R.P.S. is fresh in the minds of all), who might be taken to represent English work, and yet, strange to say, none of the nine photographs he sends represent English scenes. Venice and Holland furnish the scenes by which he is represented, and one central panel is devoted to these; even the arrangement of these, we understand, was indicated by Mr. Lewis. While the delightful grouping of his Venetian groups was much admired probably the luminous

atmosphere of "A Misty, Misty Morning in Venice," gained the most attention amongst the photographic audience.

It was a happy thought of the Salon Committee to include a very comprehensive exhibit of the work of D. O. Hill, the pioneer of pictorial photography in Scotland, if not in a wider area. For these exhibits they were indebted to Mr. J. Craig Annan, Glasgow, and Mr. Andrew Elliott, Edinburgh, and we question of a finer exhibition of these prints, dating back sixty years has ever been shown together. The framed specimens occupied one panel, while the unframed prints were contained in three cases. The quality of these early examples of photography was beyond reproach, and it is noteworthy, with all our modern improvements, that they quite merited their place in the Salon, apart altogether from their historical value.

William Crooke, Edinburgh, is the largest contributor to the Salon, and needless to say, the large number (twelve) of his pictures detracts none from their quality. Here we have portraiture at its highest. There is his famous group—triumphing over technical difficulties—at the "Edinburgh Town Council." The lovely "Zuleika" attracts us by its daring lighting; "Master Hector Macdonald," the son of Scotland's modern military hero, showed a subdued boyishness that we feel is just right; the "Infant Son of the Earl of Tankerville," is a splendid example of the modelling of the nude figure; intellectual strength is clearly shadowed forth in his celebrated "The late Sheriff Cormie Thomson, K.C."; the pathetic beauty of "Lady Leonfield"; the Scottish sagacity limned in his portrait of "Dr. Andrew Carnegie"—but why say more, the limitations of space forbid a detailed notice.

J. Craig Annan, although not so numerously represented, leaves his imprint on the visitor. His "The Etching Printer," with its masses of light and shade, entrances us as of yore; in "Harry Alfred Long, Esq.," we have a sympathetic rendition of Glasgow's Grand Old Man; "George J. Frampton, Esq.," pictures artistic manliness; while in "Frau Muthasius" we have a "strong" portrait of feminine beauty, as opposed to the "prettiness" of which we see so much nowadays.

Archibald Cochrane has only two prints, "The Sculptor" and "The Teamster," both telling pictures and artistic successes, and their presence there clearly indicates Mr. Cochrane's sympathy with the movement initiated in this exhibition.

John Spark, Perth, has been successful in having a large exhibit well hung; he has nothing to be ashamed of, his work being of a high standard. We might specially instance his "In Pensive Mood." Here the whole picture well bears out the title, and may well be marked down a success.

James Auld, Edinburgh, is represented by two prints. "A Study of a Head" is a beautiful representation of female loveliness; while his "W. Beattie-Brown, Esq., R.S.A.," is on the other end of the scale and depicts aged virility.

Arthur Hawes, Ayr, is represented by portraiture and also an effective quayside picture. His "Beauty's Eyes" merited much attention.

James Patrick, Edinburgh is represented by three pictures that have been previously medalled. His "The Evening of Life" is a singularly effective treatment of the title, the old wife and the after-glow in the sky combining to form a harmonious whole. "A Shepherd's Care" and "A Stilly Hamlet Home that vies with any Earthly Paradise," show that masterly treatment of sheep and landscape indented with Mr. Patrick's name.

W. Drummond Young and Sons, Edinburgh, have an attention-commanding print in "Evening on the Mississippi," in which the high lights in the sky and on the water appear in a brilliant orange tint.

John Hepburn, Glasgow, shows some satisfying old-world interiors. J. Kirk, Brechin, has also a fine specimen of this class of work.

V. C. Baird, Broughty-Ferry, is particularly strong in architectural work; and J. and G. A. Jack, Airdrie, have two telling pictures in this class of work.

John Smith, Dundee, makes a strong bid, with much success, for a place in genre work, and his delineations of Dundee slum life will live long in the memory of those privileged to see them.

J. W. Eadie, Airdrie, shows that his artistic abilities do not all run to friezes and stencils. Amongst other good things he shows a charming picture of "Ethel."

Archibald Campbell, Dundee, Treasurer of the Federation, shows that he is more than "a man of figures," his renderings of the dreariness of winter being picturesquely dreary.

C. D. Macdougall, Dundee, one of the Federation's Vice-presidents,

exhibits in "gum-bi," as also does A. W. Hill, Lochboisdale, George L. A. Blair, Paisley. John Richie, Kilmalcolm, has a picture in "We hail thee! Eastern gems, to cheer our Winter's Gloom" (chrysanthemums), in which the texture of the petals is well retained. A. Allan, Ratho, is represented by his "auld wife" studies, as effective as ever. J. Peat Millar has some charming little pictures; J. Dunlop, Motherwell, in "Old Scotchman" has a strong head of old man; F. W. Urquhart, Dingwall, in "The Old Fiddler" recalls some of the veteran "fiddlers" (as opposed to "violinists") of bygone days. J. S. Lamb, London, in "Evening Glow," has a picture of rare quality; Alexander McDuff, Glasgow, has a dainty little picture in "Evening"; J. C. Robertson, Brechin, shows a "symphony grey" in "The Storm Clearing," daring yet effective; J. L. Siewring, Newport, sends a typical picture in "Fisherfolk"; W. S. Crook, Glasgow (winner of the lantern slide competition) has some guard trees strongly limned against the sky. "A Bend in the Road"; "Evening on the Clyde," by W. G. McLachlan, Glasgow, is a telling picture of work—the sky is perhaps a little "loud"; "An Autumn Morning" by W. Mulroy, Glasgow, is an effective rendering of the morning struggling through the mists.

But space forbids further details. There are few really bad pictures in the whole exhibition. It is a telling refutation of the statement that there was not sufficient photographic ability in Scotland to hold a satisfactory exhibition without outside assistance.

The next exhibition is to be held in Glasgow, opening on 1 February, 1905, and we are certain, now that this exhibition secured a position, and a high position, for itself, that it will be increasing success.

THE NEW "GRAPHIC" PREMISES.

AFTER more than a quarter of a century's development and extension on its old site in the Strand and Milford Lane the "Graphic" has been removed to new premises in Tallis Street, where all departments will be under one roof. The new building is situated close to the Victoria Embankment, and is built of stone and brick. The Tallis Street frontage, of about 100 feet, is opposite Guildhall School of Music, and the building has, besides, a frontage of 50 feet in John Carpenter Street and Carmelite Street, which on either side of it. Each of the six floors has an area of 5,000 square feet, and there is accommodation for 800 workpeople. A pair of handsome oak doors give entrance to the managerial and editorial departments in Tallis Street, and an oak staircase leads to the first floor from the oak waiting-room and vestibule. A corridor runs through this floor, and communicates with the office of the managing director, the art editors of the "Graphic," "Daily Graphic," the artists' rooms, the secretarial departments and offices, and the business departments. On the second floor the rooms of the literary editor and the offices of the "Bystander." The admirable lighting of all the rooms is very noticeable—the tiled construction of the building has given special facilities to a spacious and airy effect. The rooms are fitted with mahogany, and are of a pleasantly coloured chocolate tint, which serves as an effective background for the black-and-white drawings and colour plates with which they are hung.

Besides the principal entrance, the publishing department has its own entrance, while the door by which the workmen are admitted is in Carmelite Street, and leads by a fireproof staircase to several departments. A similar door and staircase in John Carpenter Street is used for the delivery and despatch of materials. Paper, of varying kinds and sizes, is stored on the ground floor ready for use in the machine basement.

On successive floors, beginning with the basements, are the printing machine departments, the warehouse and publishing departments, the engravers' rooms, the folding and stitching departments, the composing-room, and the foundry. The composing-room, which is in direct communication with the foundry on the same floor, is a bright and airy room, lighted from above with electric glow-lamps over the type cases of each compositor. A quantity of printing matter, stories, articles, sketches and serials, has to be kept up ready for use, so that many tons of type are kept in the room made for this purpose. A very large composing staff is necessary, as the duty of fitting the illustration blocks into the pages on which the blocks and literary matter appear together has been delegated

to them. A staff of engravers is continually employed at the "Graphic" in restoring to the printed blocks the tones and artistic feeling of the original drawings. Each engraver is provided with the photo-mechanical block and a specially inked print which has been "pulled" from it. The special print shows him the best effect that can be produced from the block, better, that is, than the best that can be produced by the hasty printing of numerous copies. Thus he has a very delicate task in the calculation of the exact amount of additional engraving the block requires, bearing in mind the result of rapid printing by machinery from replicas of the altered block. Effects in the artist's drawing, which are lost in the block, must be given just the right amount of emphasis, the whites and blacks must be restored, attention has to be paid to a hundred details of the artistic technique which the block is apt to miss, for engraving is itself a fine art, since the engraver has often to restore not only the technique but the artistic feeling of a drawing. The drawing once processed, engraved and approved, the block passes on to the foundry.

Here casts are made from it. A thin layer of plaster of Paris and water of uniform thickness is spread over a sheet of paper. The paper is then placed immediately face downwards on the engraved copper plate. A blanket is wrapped round the plate, and it is then put in a hydraulic press capable of a pressure of several tons. This presses the plaster of Paris into every minutest line and scratch on the plate. The same process is equally available for advertisement pages. When the pressure has done its work, the plaster of Paris mould is slowly baked in an open oven. A cast has now to be made of the plaster of Paris mould. It is placed face downwards, and slightly warmed to prepare it for the ordeal to which it is to be subjected. It is then placed between two iron covers, and is firmly fastened face upwards, and a ladleful of molten stereo-metal, a mixture of lead and antimony, carefully heated to a certain temperature, is poured between the two iron covers, where, as it cools, it takes the impression of the plaster of Paris, and the cast is made. It is not yet, however, completed. It has to be washed in cold water, its back is made perfectly level and even by machinery, a circular saw planes its edges, and a third machine, known as a "router," smooths away superfluous metal from its face. Great care has to be taken by the workmen in control of this machine lest it should "rout" out type that should be left standing. Finally, a small slanting bevel is cut on the plate, so that it may be slipped on to the machines. All machinery is run by electricity.

The plate is now prepared for the coating of nickel, which will make it sufficiently hard for the printing of a large impression. After a preparatory washing with potash to remove any possible grease, it is given a very thin film of copper in the copper electrolysis bath; this facilitates the putting on of the nickel facing afterwards. Thirty minutes' immersion in the nickel bath are necessary to give a coat of the requisite thickness. From it may then be printed 10,000 impressions without its showing signs of wear. The completion of the plate after its leaving the engraver's hands takes two and a quarter hours. Other processes are, however, employed. There is the wax process of electrotyping, in which the planing and general preparation are the same, but which takes four hours. The plate in this process is moulded in wax instead of plaster, and is coated with copper instead of nickel, remaining for two hours in the copper electrolytic cell. For plain pages of type, *papier maché* is used instead of plaster or wax.

From the foundry the page, with its illustrations and printed matter, goes to the basement, where it is placed upon the machines. The eight new machines, which run at the rate of from 2,500 to 3,000 impressions an hour, produce the highest class of work at a greater speed than has hitherto been possible. They have been made in England, and are worked by electricity. A ten-horsepower motor, fed from an external source of supply, is geared to each machine. A machine manager can control the speed of the motor by means of a regulator with which each machine is fitted. The row of machines extends right along the north front of the buildings; opposite each are boards with the number of the machine and the implements belonging to it. The electric switch-room is adjacent to the machine-room. It is supplied by mains from the two electric power companies, and thence from the switch-boards provided there to the other machines throughout the various departments. On coming from the machines the printed sheets are stacked

on trucks and sent by lift to the third floor, and wheeled to the warehouse department. Here they are folded and stitched by machines, which are also driven electrically. The finished copies are then packed in bundles and sent by a second lift to the publishing department. The work of this department has to be greatly specialised. The great number of copies sent to so widely different destinations necessitates continual work by night and day to supply the various agencies, while the work of preparing extra, special, and Christmas numbers sometimes necessitates organisation many weeks beforehand, and sometimes takes the efforts of all concerned to produce them in as many days.

The necessity of finding extra space for the colour printing department was the first step towards leaving the old "Graphic" premises in Milford Lane. The works established at Reading are arranged on one floor, with north lights extending from end to end. The machines are all in line. A private roadway leads to the main building, which it enters by an arch. In the roof of this archway a long girder with travelling pulleys lifts the heavy cases in which the finished publications are sent to the London office. The principal processes employed are the multiple-colour and the three-colour process. In the former and older process as many as eight or more plates are used. The first plate prints the principal lines of the picture, and successive plates add the various colours. It is a long process, and the resultant colours may differ considerably from the original picture, as well as from one another. In the new process three colours only are used. They are obtained by methods similar to those used in three-colour photography, in which an object is first photographed through coloured glasses that exclude superfluous rays and colours, after which the negatives obtained by this means are superimposed. The greatest exactness is required in the superimposition of the colour plates in colour printing. If the plate of any colour is a hair's breadth "out of register" in the first or second printing, the finished picture is spoilt.

In the Reading works, as at Tallis Street, each machine is driven by its individual electric motor. Electricity allows of a subdivision and regulation of power which is indispensable in such delicate work. The plates for the printing works are all made in the electro department at Tallis Street. Besides the manager of the Reading colour printing works, an art sub-manager, who is responsible for the exact colouring required in the plates, goes between the Tallis Street and Reading works. The Reading works also communicate with the London office by telephone, and telephonic communication is established between every room and every department.

The Adhesive Dry Mounting Company, Limited, are giving demonstrations of the process to which we referred in a lengthy article in our issue of June 26th last, at their premises, 27 and 28, Fetter Lane, London, E.C.

SCIENTIFIC Kite Flying.—At the ordinary meeting of the Royal Meteorological Society, held last week, at the Institution of Civil Engineers, Great George Street, Westminster, the President, Captain Wilson-Barker, in the chair, a paper was read by Mr. W. H. Dines on "Observations by Means of Kites at Crinan in the Summer of 1903." The weather was exceptionally unfavourable to experiments, not only for the large amount of rain, the measurement for the month of August being 8.62in., but thunder storms and gales were more serious interfering causes than the rain. On twenty days out of the thirty-one the wind attained the force of a moderate gale in the district. One of the kites used was 12ft. high, and had 156 square feet of lifting power, its weight being approximately 20lb. Observations were obtained to the height of about 6,000ft. on several occasions, and once to the height of about 8,000ft. A self-registering thermograph was raised, and its resulting observations proved very satisfactory. Various layers of air were observed, strata of dry air alternating with strata of very damp or saturated air. There was, as usual, a decrease of temperature with elevation, and the observations prove that in free air the decrease of temperature with height is less than where there is the interfering cause of land. The decrease of temperature for the height of Ben Nevis is about 5 deg. or 6 deg. less than is shown by the observations at Ben Nevis itself. The mean decrease of temperature for the first 5,000ft. was, during last August, 3 deg. 2' for each 1,000 ft., which is substantially the same as that obtained in the preceding summer, although the conditions of weather were very different. These observations are likely to supply data of much scientific value.

THE "L. AND P." SUPPER.

(BY ONE WHO WAS PRESENT.)

AFTER a lapse of some fifteen years the London and Provincial Photographic Association recommenced on the 9th February, 1899, its series of annual supper and social evenings. Thus the function held at the Association's rooms on Thursday last was the sixth of the series. The affair this year served a double purpose, for in addition to being the annual social it gave occasion to welcome back to the Association, and to the photographic world, Mr. E. J. Wall, who presided. Mr. Wall, it will be remembered, met with a terrible accident over two years ago, and after much suffering has almost recovered from the injuries he then received. The evening of the supper was, as Mr. Bedding when proposing the chairman's health aptly termed it, Mr. Wall's "first night out." The supper was timed for 7.30, and a few minutes afterwards, upwards of seventy members and friends sat down to a supper, described on the menu as "Julienne soup, boiled leg of mutton and capar sauce, roast ribs of beef, Yorkshire pudding, vegetables in season, college pudding, apple tart, jellies, cheese and celery." No liquid refreshments, it will be seen, were listed, and considerable difficulty was experienced by one and all in getting even a popular "bitter," so busily engaged were the three attendant Hebes in the gentle pastime of juggling with the plates. When their performance was nearly at an end, and the chairman and some others had threatened to drink the water out of the celery glasses a boy appeared, and after considerable palaver produced a bottle, then another and then another, and finally some glasses. It was at this stage of the proceedings that the company settled down for a comfortable and jovial evening.

After the usual loyal toasts, the "L. and P.P.A." was proposed by Mr. Wall, and Mr. A. Haddon, one of the trustees, responded. The toast of this particular evening was in the hands of Mr. Thomas Bedding, who in an eloquent speech gave "The Chairman," to which Mr. Wall suitably replied; saying that he hoped now to be again a constant visitor to the Thursday evening meetings of the L. and P. Mr. R. P. Drage in his usual genial manner, submitted the toast of "The Officers," to which Mr. R. J. Kindon, the popular hon. secretary, replied, in a brilliant speech full of witticism: "No better man than Mr. S. H. Fry could have been found to take the toast of 'The Press,'" to which Mr. R. C. Bayley replied. The "L. and P.P.A." has always encouraged visitors, and the large number present were toasted by Mr. T. E. Freshwater. Mr. J. T. Ashby humorously replied.

Then we had "Absent Members," by Mr. W. D. Welford, and messages were read from Mr. A. L. Henderson, who is now travelling abroad, and from Mr. Furley Lewis, who was unable to be present on account of illness. Among those present I noticed, in addition to the speakers named above, Messrs. A. Mackie, R. R. Beard, T. K. Grant, H. Vivian Hyde, H. C. Rapson, J. E. Hodd, J. W. Hodges, R. H. Anthony, T. Thorne Baker, Wilfred Emery, J. A. Sinclair, P. R. Salmon, R. Beckett, H. Snowden Ward, J. W. Zaehnsdorf, J. S. Teape, E. T. Wright and W. T. Wilkinson.

The musical programme has always been—at least while Mr. T. K. Grant has had it in hand, and that is several years now—an important item, and one not to be missed. This year was no exception to the rule. Mr. Grant himself has a fine tenor voice, and his two songs pleased the company immensely. Mr. James Campbell, of the Palace Theatre, one of the neatest and most versatile mimics of the time, gave some lifelike imitations of Mr. Arthur Roberts, Mr. Dan Leno, and other stars; Mr. George Robins treated the company to humorous sketches, Mr. P. Payne and Mr. G. A. Arnold sang comic songs; while Mr. H. Vivian Hyde, with his rich mellow voice, gave two suitable songs.

At eleven o'clock "Auld Lang Syne" was sung, and the company broke up, and as I took my way from the "Jovial Throng" I fell to wondering at the meaning of the mystic words uttered by several of my fellow roysterers. These were: "Well!" "However!" "I see!" "I must go now," "I must really at last expedite my departure," and so forth. Can you enlighten me, sir?

New Books.

"Kamera Kunst." Verlag von Gustav Schmidt. Berlin.

We have received a copy of this work, which purports to be a collection of pictures, with descriptive text, to show the efforts made by photographers in various countries to give individuality and artistic feeling to their work by new methods. Photography is comparatively a young art, and it is no doubt desirable that restrictions should not be placed upon the selection of the medium, or the way in which it should be used. But it does not follow that the work which may be produced under such conditions must be artistic because of its novelty. Yet, such appears to be the basis upon which the claims of some modern pictures appear to rest. A careful study of this collection will, we are convinced, lead to the conclusion that many are bad, and have no claim to be classed as works of art, even in the photographic sense of that much-abused term. We might even go further, and pronounce some of them mere studies, suggestive of human deformity. On the other hand, there are a certain number of pictures which compel admiration for the skill of the photographer. The book, in a measure, represents the tendency of so-called modern photography, a movement which should be regarded with toleration in the hope that some good may eventually come from it.

Patent News.

The following applications for patents were made between February 8th and February 13th, 1904:—

Automatic Machine.—No. 3,093. "An improved automatic photographic machine." (Ernest Hopkinson, United States.) Complete specification. Henry Conrad Heide.

Processes and Emulsions.—No. 3,107. "Improvements in and relating to photographic processes and emulsions." Andrew Wybrat Penrose.

Hand Camera.—No. 3,162. "An improved photographic hand camera." Harry Binfield Parish.

Shutter.—No. 3,272. "An improved photographic shutter." Walter Frederick Giles.

Printing Apparatus.—No. 3,382. "Improvements in photographic printing apparatus." Herbert Richard Watts.

Printing Frames.—No. 3,648. "Improvements in photographic printing frames and hinges to be used on the same." Complete specification. Henry James Spratt, Alfred Sidney Spratt, and George Albert Spratt.

Printing Frames.—No. 3,687. "Improvements in or relating to photographic printing frames." (Frank A. Brownell, United States.) Kodak, Limited.

Enlarging Cameras.—No. 3,695. "Improvements in or relating to photographic enlarging cameras." (Frank A. Brownell, United States.) Kodak, Limited.

THE Metric System.—The Liverpool Chamber of Commerce has forwarded to Lord Avebury, for presentation to the House of Lords, a memorial on the subject of the metric system of weights and measures. The memorial recites the steps which have been taken in recent years to have the system adopted in this country by Chambers of Commerce and other kindred Associations, and points out that in most of the countries of Europe and South America the metric system obtains. The memorial prays that the House of Lords will do their utmost to pass the Bill providing for the compulsory adoption of the system within a reasonable time, as recommended by the Select Committee of the House of Commons which reported on the subject in 1895.

Exhibitions.

LONGTON AND DISTRICT PHOTOGRAPHIC SOCIETY.

The following were the awards at this exhibition:—

OPEN CLASSES.

Portraiture.—Gold medal for champion picture of the exhibition, Arthur Marshall, Nottingham, for "My Little Dutch" (carbon); bronze medal, F. J. Mortimer (Portsmouth), portrait study; extra bronze medal, F. A. Swaine (Southsea), "Morning Service."

Landscape, Seascape, etc.—Silver medal, F. J. Mortimer, marine study, "In the Height of the Storm"; bronze medal, W. Clayden (Lymington), "A Misty Morn"; extra bronze medal, J. B. Johnston (Edinburgh), "Homewards."

Architecture, Flowers, etc.—Silver medal, P. W. Crane (Hleanor), "Crypt de l'Aquilon"; bronze medal, S. G. Kimber (Southampton), "The Monks' Entrance."

Lantern Slides.—Silver medal, F. G. Tryhorn (London); bronze medal, Geo. A. Booth (Preston).

OPEN LOCAL CLASS.

Any Subject.—Silver medal, Thomas Warham (Audley), "Evening at the Mawddach"; bronze medal, W. H. Foxall (Tunstall), "When Evening's Twilight Gathers Round."

MEMBERS' CLASSES.

Portraiture.—Silver medal, W. H. Foxall, study of an old man's head; bronze medal, withheld.

Landscape, Seascape, etc.—Silver medal, Rev. C. F. L. Barnwell (Ramshill Vicarage), "In the Country of Adam Bode"; bronze medal, T. W. Hawksworth (Leek), "Where the Tide Turns."

Architecture, Flowers, etc.—Silver medal, W. H. Foxall, still life group; bronze medal, Rev. C. F. L. Barnwell, "Bath Abbey."

Enlargements.—Silver medal, W. H. Foxall, "A Woodland Path"; bronze medal, S. Jackson (Longton), "Old Irish Cottage."

Instantaneous.—Silver medal, Rev. C. F. L. Barnwell, "The Fishing Fleet"; bronze medal, W. H. Foxall, "Under Parental Care."

Picture Postcards.—Bronze medal, Thos. Hartley (Bosford), "Norfolk Sands, Blackpool."

Stereoscopic.—Bronze medal, S. Jackson, "Winter Sunshine."

Beginners' Class.—Any Subject.—Bronze medal, A. E. Cox, bromide enlargement of a waterfall.

Lantern Slides.—Silver medal, W. Bates (Longton); bronze medal, Ashworth (Fenton).

EXHIBITION OF PHOTOGRAPHS ON LUNA PAPER.

A LITTLE exhibition is now being held at the Regent Gallery, 69, Regent Street, W., of photographs printed on Luna paper. The particular feature of the paper is that, unlike ordinary papers in which the sensitising compound is in the form of an emulsion; the sensitising material is incorporated in the substance of the paper, and is not merely upon the surface. The advantages claimed from the adoption of this method, which is equally applicable to textile fabrics as a base, is that the image is of a depth and richness which is practically unattainable when it is merely a surface image, that there is no tendency to curling during manipulation or in the finished print; that cracks, blisters, or reticulation are impossible; and that a great range of tones are attainable with the same toning bath. The paper may be printed on either side with practically the same result. In practice, the paper is printed in the usual way, or it may be partly printed developed. After printing, it is washed until the washing water is free from milkiness, and toned in a chloroplatinite bath. The toning is exceedingly rapid, less than ten minutes being required for black tones. An acid fixing bath is employed, and the subsequent washing is performed in the usual way. Alternately, many of the ordinary gold-baths may be used. The exhibition is held in a very pleasant little gallery, and is open, free, to the public. Amongst the examples shown are several more than average interest, which show that the advantages claimed for the paper, or, at any rate, some of them, are not undervalued. Particularly noticeable were those pictures in which silk and other textile fabrics formed the base. It is evident that pleasant tones are attainable at whatever stage the print is removed from the toning bath, and the colours vary from a pronounced red to a very good black. A series of prints from the same negative illustrate the point very well.

In addition to the prints, some transparencies which are also exhibited are worthy of notice. The base consists of a translucent paper, and the sensitising material is the same as that used for Luna paper, the treatment being the same. The results shown are indistinguishable from transparencies made on glass plates, as far as grain is concerned, but they have the advantage of the range of colours natural to the process under the action of the toning bath.

KODAK EXHIBITION OF PHOTOGRAPHS OF JAPAN.

TAKING advantage of the interest the outbreak of war in the Far East has stimulated in Japan and the Japanese, the Kodak Company has organised an exhibition of photographs illustrative of the scenery of Japan and the manners and customs of its inhabitants. The exhibition is at the Kodak Gallery, 40, Strand, W.C., and will remain open, free, for some time. The pictures are all enlargements upon bromide paper, and have been produced at the Kodak factory at Harrow. The original negatives, with but few exceptions, were upon rollable film, and have been taken in a Kodak.

The pictures, which number a few short of 150, do not constitute a series made upon a settled plan to illustrate the subject, but they are hardly less interesting on that account. The intelligent traveller who uses a hand camera to make records of his travels, naturally chooses the most typical scenery of the lands he visits, the most famous monuments, and the incidents of life which least accord with his ordinary experience, to commemorate, and although perhaps the joint efforts of even a number of casual visitors may fail to give an insight into the inner life of a people, the general aspect, as it strikes a visitor, of a country and its inhabitants is almost as well presented in a scratch collection of photographs by many people as it would be in a series more elaborately projected. At any rate, the collection of photographs now on view greatly helps one to realise what a marvellous upheaval the adoption of Western ideas by the Japanese nation is accomplishing, and it is well worth a visit, if only to acquire some of the local colour of the events which are now agitating the civilised world.

The object of the exhibition is, of course, primarily to advertise the excellence of the Kodak Company's manufactures, and this it very successfully does in demonstrating that Kodak film negatives made in the ordinary way will enlarge many diameters without an appreciable loss in any way of their original quality. It is really an excellent exhibition of photographic work, and, in these days of aggressive advertising, we cannot help feeling grateful to the Kodak Company for having adopted a method of furthering their own interests which is not only inoffensive, but of benefit to those who come within its influence.

Most of the pictures were taken by Mrs. Lazenby Liberty, Miss Davidson, Messrs. G. Ralph Cox, F. F. Paget, and Adam Sykes, but there are also some very fine portraits—members of the Japanese Legation, etc.—by Messrs W. and D. Downey.

FORTHCOMING EXHIBITIONS.

February 27 to March 5.—Birmingham Photographic Society. Particulars of L. Lloyd Hollies, Church Road, Moseley, Birmingham.

February 29 to March 3.—Cripplegate Photographic Society. Hon. Secretary, George H. Depledge, 17, Hazeldene Road, Goodmayes, Chadwell, Essex.

March 5.—South London Photographic Society. W. Calder Marshall, F.C.A., 41, Glenton Road, Lee, S.E.

March 5-12.—Brechin Photographic Association. Hon. Secretary, J. Kirk, 1, Infirmary Street, Brechin.

March 8-9.—G.E.R. Mechanics' Institution (photographic section). Hon. secretary, A. Woolford, 16, Grove Green Road, Leytonstone.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 22 to April 5.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
26.....	Aberdeen Photographic Assoc.	<i>Advertisements.</i> Illustrated. Mr. W. P. Webster.
26.....	Watford Photographic Union	Open Night.
26.....	Glasgow Southern Photo. Assoc.	Social Evening.

3.....	Hull Photographic Society	<i>Photographic News Prize Slides.</i>
3.....	Glasgow Southern Photo. Assoc.	<i>Portrait Printing.</i> Illustrated. Mr. Thos. Rennie.

CAMERA CLUB.

PHOTOGRAPHY has been for a long time so intimately associated with astronomy that Mr. Maender's lecture last week on the "Canals of Mars" aroused much interest among the members of the club, and drew a large audience. Captain Hills occupied the chair and introduced the lecturer. Mr. Maender acknowledged that there was no other club or society before which he would have greater pleasure in appearing as a lecturer, for the debt of astronomy to photography was beyond all calculation. It had multiplied by ten the effectiveness of the astronomer's instruments, and have divided by ten his difficulties. He was sorry, therefore, that the subject of his address would not be more photographic in character. He was to speak to them of the planet Mars, and planetary photography, for reasons which he would refer to later on, had made little headway. Mars is invested with greater interest for us than any of the other wanderers in space. Of course, we had our far more conspicuous satellite, but the moon was ever the same. Jupiter, the giant planet, showed abundance of change. Saturn was more beautiful, but it was too far off for any details to be observed. Venus was brighter than Mars, but its cloudy envelope veiled any details which might otherwise be apparent. Mars was usually clear, and for the past two centuries its distinct markings had been mapped by several careful observers, and it was noteworthy that several of the features depicted in the earliest charts were recognisable in the most modern ones. In looking through a telescope at Mars we see a very small object in the middle of a wide field, and to give some idea to those who are not astronomers as to what Mars looks like, he would say that it appears, in a telescope of high power, very much like the moon as seen through a child's spy-glass, having a magnification of two or three diameters. The orbit of Mars when compared with that of the earth is eccentric, and therefore the planet is much nearer to us at certain times. In 1877 it was at its nearest possible point to the orbit of the earth, and many astronomers took this opportunity of studying the planet and making drawings of it. And among these might be specially mentioned Nathaniel Green, whose drawings of Mars were certainly the best ever made. Comparing these drawings with the older ones by Beer and Mädler it was quite evident that the chief markings on the surface of Mars were of a permanent character.

The year 1877 was also noteworthy with regard to observations of Mars, because in that year Schiaparelli announced the discovery on the planet of a great number of channels (canals). This was a somewhat unfortunate term to apply to these markings, because a canal is an artificial construction, which carries with it the idea of human handiwork, and thus the inference drawn was that Mars was an in-

habited globe like our own. This discovery excited the greatest interest, and many observers looked for, and found, the canals.

The next prominent observer of Mars was the American astronomer Mr. Lowell, who built for himself an observatory at Arizona, and devoted himself to planetary research. He drew many detailed charts of Mars and found there many more canals than his Italian predecessor had done. In fact, on the chart which he drew, these canals appeared as a most complicated network, and the system covers, not only what is regarded as the land portions of the planet, but the lighter "sea" portions as well. So complex is the system as described on this chart that it is difficult to recognise many of the old permanent features of the planet. Mr. Lowell confessed that the appearances seemed to him to be unnatural, and thought that the canals were perhaps the work of intelligent beings, due in the first place to the melting of the snows at the polar regions of the planet, and subsequently devoted to purposes of irrigation. He corroborated Schiaparelli's observations that the markings changed with the seasons.

The year 1877 is also remarkable for the discovery of the satellites of Mars—Phobos and Decimos, as they were subsequently named. They give little light to the planet, and they are so small that they can exert very little tidal influence, so they may be regarded as useless to Mars. But they have helped our astronomers to determine the mass of the planet. And they have been able to estimate the atmospheric pressure, and the amount of heat which Mars receives from the sun, only about half as much as this earth gets. This would render the presence of life as we know it almost impossible, hence it came to be thought that Mr. Lowell was wrong in his canal theory.

It might be asked, "Why not settle the point once for all by means of photography?" But the camera cannot help us here. The planet is always revolving on its axis for one thing, and for another its prevailing colours are orange and deep yellow. Moreover, the dark markings are bluish grey, and when an object with such colouring is presented to the lens the photographer is powerless, unless he adopts such expedients as are out of the question when dealing with such a distant and moving body as Mars. And it must be remembered, too, that Mars is an exceedingly small object when compared, for example, with the moon. It could easily be put into one of the smaller lunar craters.

When Mr. Lowell subsequently stated that he had also found a network of canals on Venus, it began to be suspected that the Martian canals were possibly due to the personal equation, and that Mr. Lowell's observations were the result of an optical illusion. The lecturer had made a number of experiments, and he had come to the conclusion that when a surface was covered with dots or any irregular markings, and was viewed from a certain distance, there was a tendency in the observer to link those markings together into straight lines. He then hit upon the expedient of making a drawing of Mars, in which the canals were replaced by such irregular markings, and he placed that drawing before a number of boys, who were seated at different distances from it, and they were directed to make as truthful a copy of it as they could. They all drew in the canals, although canals were non-existent in the original. It was amusing, said the lecturer, to hear the boy's remarks as they afterwards crowded round the drawing. "Why there are no lines," said they, and evidently thought they had been hoaxed. Mars had been hoaxing the astronomers in the same way. There were no markings upon it which gave any evidence of life.

A long and animated discussion followed this most interesting lecture, in which Mr. Porter took up the cudgels on behalf of Mr. Lowell. He, too, had experimented with his own pupils in much the same way as Mr. Maender had done with his class of boys, but the results were not similar. The proceedings closed at an unusually late hour, with the customary compliments.

SOUTHSEA PHOTOGRAPHIC SOCIETY.

FEBRUARY 17TH.—Reports from the treasurer (Mr. F. S. Hoyte) and assistant hon. secretary (Mr. F. J. Lawton) gave evidence of the sound financial condition of the Society, and its efforts on behalf of its members' interest. The following executive was elected:—President, Mr. H. T. Lilley, M.A.; vice-presidents, Mr. Fisher, A.S.A., Mr. L. G. Bonham Carter, and Mr. H. J. Hissett; hon. treasurer, Mr. F. S. Hoyte; hon. secretary, Mr. F. J. Lawton, 20, Clarence Square, Gosport; assistant hon. secretary, Mr. Gilbert Wood, A.R.I.B.A.; hon. lanternist, Mr. E. H. Purvis; council, Dr.

lips, Messrs. S. O. Black, W. M. Cliffe, A. B. Casey, G. Slan-
, and A. A. Lawton.

CROYDON CAMERA CLUB.

FEBRUARY 17TH.—Following two prior demonstrations, illustrating to make transparencies, and enlarged paper negatives, Mr. Lionel proceeded to show how the latter printed in carbon, and though he disavowed any intention of giving a demonstration as to the complete way in which he dealt with his subject, he nevertheless introduced itself into a capital exposition of this beautiful pigment process.

During the evening he also brought forward a new procedure introduced by the Autotype Company, patented by them, and hitherto made known. In the ordinary way, the tissue is either left in a sensitive condition, or sensitised by the user, and dried, then, as a distinct operation brought into contact under water with one of the many varieties of single transfer paper, or temporary support, as the case may be. The novelty under notice apparently lies only in tissues in an insensitive condition, and consists of producing a piece of thin unprepared paper into the sensitising process simultaneously with the tissue, both are removed together, pressed into contact, and allowed to dry. The adhering paper is made translucent by means of paraffin oil, and the tissue placed under a negative in the ordinary manner, the thin paper intervening. On exposure, the print is developed in the usual way, but it was found to be able to support it on a piece of wood, which might be allowed to float in the developing tank. The increase of exposure, owing to the interposition of the paper, it was stated, is of a negligible quantity, and if a suitable paper is chosen the grain should not be excessive. Mr. Kough also said, that the "bête noir" of carboners, namely, "blisters," had never made their appearance, and that, in printing in general, these more frequently occurred when using thick single transfer papers than with the thin ones.

The new method appears to have distinct advantages over the old, and recently suggested of printing through the paper backing the tissue. The worker has obviously a choice of papers, and a semi-transparent one is selected, a variety of pleasing effects can be secured by laying the print down on tinted or coloured supports. It would also be easy to intensify or subdue portions of a print by locally tinting or toning down the paper behind. Whether this would be advisable to lay down a paper saturated with paraffin or a negative which has been retouched is perhaps open to doubt, but it might mean removal of the medium and the retouching with it at the application of the paraffin would appear to be chiefly after affecting speed of printing, and not an essential. It was stated that any thin paper might be used, but not all papers successfully withstand soaking in water at 110 degrees Fahr. But the Autotype Company will supply a suitable paper.

The process being patented, it is not open to anyone to practise it, but it was understood that the Company would raise no objection to being worked in conjunction with the Autotype tissues. At the conclusion of Mr. Kough's demonstration, Mr. G. Noaks made a capital contact bromide prints from the same negatives, the process used being Messrs. Wellington and Ward's. The chairman, Mr. A. Salt, in proposing a vote of thanks to Messrs. Kough and Noaks, acknowledged the club's indebtedness to Mr. Sawyer for giving them an early opportunity of inspecting an interesting modification of the Autotype or carbon process.

The following letter appeared in last week's issues of the "Croydon Camera Club" and "Croydon Guardian":—

THE PRESIDENCY OF THE CROYDON CAMERA CLUB.

—May I be permitted to make known in your valued journal the methods and attitude of a section of the members have asked me to resign the Presidency of the Croydon Camera Club? I would also like to thank a host of friends who, during the past ten years, by their loyal, cordial, and energetic co-operation encouraged me to do my best for the club. To them is due the remarkable prosperity to which the club has attained. They have so to speak, toiled at the oars, set the sails, and worked the ship through many a storm, while I have done little more than steer clear of rocks and quicksands.—Faithfully yours,

HECTOR MACLEAN.

February 17th, 1904.

CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY.

A LECTURE entitled "Some Notes on Gothic Architecture," was recently delivered by Mr. J. Borthwick Panting, F.R.P.S., at the Society's headquarters. Briefly referring to the earliest types of architecture known, Mr. Panting passed through the various periods to the late Gothic. The lecturer dwelt on the necessity for a photographer to specialise if he wished to excel in any particular branch of photography, and emphasised the fact that some of the most beautiful examples of architecture were to be found in Northamptonshire. The lecture was profusely illustrated by photographs, from Mr. Panting's camera, taken in different parts of the country. A fine series of windows brought one of the most successful lantern evenings to a close.

BLAIRGOWRIE AND DISTRICT PHOTOGRAPHIC ASSOCIATION.

THE annual general meeting was held in the Photographic Rooms, Blairgowrie, Mr. John B. MacLachlan presiding. The secretary reported the results of last month's competitions. Best four prints, for special medal—1, James Donaldson; 2, Luke Falconer, jun.; 3, D. G. Monair. Mr. Donaldson having won the medal twice it becomes his own property. Best lantern slide, illustrating a quotation from Burns—1, 2, and 3, Luke Falconer, jun. The results of the session's competitions were:—Class "A," the "Macgregor" champion medal: Luke Falconer, jun., 14 points; 2, D. G. Monair, 11 points. Class "B" (Mr. J. D. Petrie's prize): George S. Grant; 2, James Richardson. Two new members were admitted. Messrs. D. G. Monair and W. D. M. Falconer, delegates to the Scottish Photographic Federation, reported as to the annual general meeting of the Federation at Perth.

The Secretary's report showed a slight decrease in membership, and the Treasurer's a substantial credit balance. Both reports were adopted. Office-bearers for the season were elected as follows:—President, A. Geekie; Vice-Presidents, D. G. Monair and W. D. M. Falconer; Secretary, Luke Falconer, jun., James Street Cottage, Blairgowrie; Treasurer, John Cameron; Auditors, James Donaldson and D. S. MacLennan; Hon. Lanternist, H. S. Fyffe; Executive, J. D. Petrie, John B. MacLachlan, James Donaldson, James Richardson, and H. D. Ross. Mr. James Patrick, S.P.F. judge, was reappointed judge of the monthly competitions. After discussion it was agreed to promote an international exhibition at Blairgowrie early next year, and it was remitted to the Executive to make arrangements for the same. A draft syllabus for the session was submitted, and, with slight alterations, approved.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.

FEBRUARY 8th.—At the monthly meeting, Mr. Brown, F.R.S., gave a lecture on "Halation." The President, Mr. David Elliott, B.A., was in the chair, and there was a large attendance of members and friends.

Mr. Brown suggested first that in carrying out any process in the arts it was desirable not only to know how to do it, but also how it was done—i.e., to understand the scientific theories underlying the art. This knowledge gave an intelligent interest even to so simple a matter as that described by the title of his paper. Halation was, as all photographers knew, a sort of local fogging or "halo," which appeared round the high lights in a picture, causing indistinct contrasts, sometimes even blotting out details, such as in branches of trees against the sky, or the mullions of windows when interiors were being photographed. That the effect could be avoided was illustrated by a number of very beautiful prints from negatives by Mr. R. Welch, under what might be called very trying circumstances—photographically speaking. Mr. Welch was here, as always, the amateur photographer's friend, and the help kindly given to the members of that association in its embryonic days was always gratefully remembered. The lecturer then explained that halation was due to stray rays of light that had passed through the film when a plate was being exposed, and, after passing through the glass, were reflected to the back, or underside of the film. If such rays entered the glass at an angle other than 90 degrees they were reflected to one side or other of their point of entry, and thus caused the film to blacken on development in a wrong place. That much reflection took place was illustrated by an observation of the two images of a candle flame seen in its reflection from a plain glass

plate, or if the fine images that appeared (if the glass were silvered on the back) as in looking-glasses. In order to prevent halation it was only necessary to prevent the stray rays referred to from reaching the film, and this might be accomplished in two ways. One was to use a very thick coating on the plate, so thick that very little light could pass through it to enter the glass. This, however, involved a costly coating, and was not so efficient as the alternate method, even with a coating of the usual thickness through which light easily passed to the glass under it. Inconvenient light in photographic apparatus was usually got rid of by absorbing it by a blackened surface, a black or red pigment. As such pigment could not be put into the glass plate itself without obvious objections, it became necessary to induce the objectionable light to come out of the glass, to come out and be killed as it were, instead of being reflected back to the film. It was pointed out that when light passes from one transparent medium (in this case, glass) into another (in this case, air), part of the light was reflected without change if the dividing surface was polished, and that the amount of light so reflected depended on the indices of refraction of the two media. If these were equal no reflection occurred. It was therefore only necessary to replace the air in contact with the glass by some substance having the same refractive power as glass. Canada balsam, for instance, had nearly this characteristic, and, if spread on the back of a glass plate no reflection occurred there, but all the light emerged from the glass into the balsam. The light had thus been induced to come out of the glass, and having got it out it could very easily be absorbed and got rid of by mixing with the balsam any dark pigment. This mixture of balsam and pigment was, in fact, a backing. In its construction it was to be noted that the chief matter for consideration was the nature of the medium employed to mix the paint. The colour of the pigment was of little consequence so long as it was non-actinic. To illustrate this an experiment believed to be quite novel was shown. A little flat cell or box had been prepared, one side of which was formed of a polished slab of glass, the opposite side of blackened metal. The double images of an illuminated narrow slit, as reflected from the front and back surfaces of the glass slab, were shown on the screen. The medium in contact with glass surfaces being air, considerable reflection took place, and the images were approximately equal in brightness. On filling the cell with a mixture of Canada balsam and turpentine, thus removing the air and substituting a substance with nearly the same refractive power as glass, little or no light was reflected at the back of the glass, but all passed out into the balsam and on to the blackened metal side of the cell, where it was absorbed. The second image therefore practically disappears. It was, however, sometimes desirable or interesting to compare the qualities of certain backings whose constituents were unknown. This was easily accomplished in a manner also devised by the lecturer. The backings to be compared were painted in strips across one side of a glass prism. The prism was then held horizontally with the backed side down, when the internal reflection of a candle flame or of daylight from this backed side could be readily seen. Where the glass was backed the amount of reflection was small or nil, and the quality of the backing was easily judged by the relative brightness of the image reflected at its surface. In this way it was seen that there was not a very important difference between the nearly perfect backing of balsam and lampblack and the penny India ink so long successfully used and often recommended by Mr. Welch. The very fine slides used in illustrating Mr. Brown's lecture on the various points were kindly lent by Mr. Welch. Mr. C. Mitford Martin, hon. lanternist, carefully worked the lantern. The members present learned many tips which should prove useful in the coming season, and Mr. Brown received hearty thanks from all. Samples of "halogene" for backing plates were shown. There is little mess with this excellent medium, and it dries quickly. Afterwards members tried the new "daylight developing" medium, "coxin."

The Hon. Secretary (Mr. Thomas N. Murray) announced that the Lord Mayor (Sir Otto Jaffe, J.P.), who is a member of this society, had kindly promised a gold medal for competition amongst members, which notice was received with applause. By the courtesy of Mr. Hall, managing director of Messrs. Wellington and Ward, sample negatives were sent for the use of members to judge what class of a negative should be aimed for, for enlarging purposes on bromide papers.

BURTON AND Y.M.C.A. PHOTOGRAPHIC SOCIETY. On February 15 a lecture, entitled "The Eye Compared with Camera," was delivered before the members of this society by A. W. Butterfield, who said that one could not help but notice remarkable similarity in many respects of the eye and the camera, the eye being really a camera and nothing more, though certainly a most beautiful type. As cameras in themselves are merely apparatus for the production of impressions on a plate or film, so with the eye, and in a similar way to which these impressions received on the plate at the back of the camera, so are impressions received on the plate at the retina at the back of the eye, and this by a marvellous piece of apparatus, conveyed to the brain, which is really the organ that gives the power of sight. Though a person may have a perfect eye, yet he might be unable to see, as blindness is not always due to a defect in the eye itself, the cutting of the optic nerve, or injury to the seat of vision in the brain, for instance, rendering the eye useless. In taking the component parts of the camera, the eye it would be found that the latter was far superior to the camera invented, and though, like the camera, it was fairly simple yet when examined under a microscope would be found to be a most intricate and marvellous mechanism. By means of a series of diagrams thrown on the screen it was shown that the eye and camera have their cap, lens, diaphragm, dark chamber, and plate, with their respective ports; though in the case of the eye the dark chamber is not filled with air but contains a peculiar kind of vitreous substance, which takes its place. The plate or retina of the eye, however, being curved instead of flat, as is the case with the camera plate, possesses an enormous advantage over the latter, as rays of light from distant near objects can be focussed more accurately than on a flat surface as on account of the convex nature of the photographic lens it is impossible to bring all rays to a focus on the same plane, though for all practical purposes sufficient accuracy may be attainable. A minute examination of the structure of the eye, and more especially the retina, the lecturer went on to explain the adjustment for near or short distances, pointing out the necessity of altering the distance of the lens and plate in the camera, and showing how the eye, though fixed, accommodates itself to various distances by altering the convexity of the lens. The different range of vision was next touched upon, and it was also demonstrated how the defect known as spherical aberration could be obviated to some extent by "stopping down" the process in both the eye and the camera being almost identical. A few remarks were afterwards made on the subject of binocular vision, and it was much to be regretted that time would not permit of more than a glance at colour vision, which had to be dismissed by merely touching on the fringe of one of the most interesting sections of the lecture, which had been made more intelligible by the use of an excellent set of microscopic slides and diagrams.

ROYAL Photographic Society.—The third of the series of practical demonstrations will be given at 66, Russell Square, on Tuesday, March 1st, 1904, at 8 p.m., by Mr. E. T. Holding, the subject being "Platinotype Printing." Synopsis: The negative—the varieties of paper-printing—developing (a) cold bath; (b) hot bath—modification in development for (a) under printing; (b) over printing—toning. G. Lamley will occupy the chair.

In connection with the St. Louis Exhibition, which opens on 1st, Sir Benjamin Stone, M.P., who has forwarded to America a large-sized portraits, for the display of which a separate room has been specially prepared, has written an elaborate catalogue describing the series which he has selected to illustrate the educational value of his collection, the object of which is to preserve a pictorial record of current British life and history. The principal subjects depicted are the May Day Festival at Knutsford, the Corby Pole Fair, the Welsh Eisteddfod, Tynwald Day in the Isle of Man, the Corn Law Array at Lichfield, the Stratford-on-Avon Mop, the Hock-Tid-Hungerford, the distribution of the Maids' Charity at Biddenden, Baal Fires of Northumberland, the Horn Dance at Abbots Bromley, the collection of Wroth Money at Knightlow Hill in Warwickshire, Garlands' Day at Abbotsbury, the Tissington Well-dressing, various incidents and scenes of historical interest in connection with places in London, such as the Tower, the Houses of Parliament, Westminster Abbey, and the old Christ's Hospital.

Commercial & Legal Intelligence

are asked to state that the Debentures issued by Speaight, and the child photographers, in connection with the building of new Bond Street Studios, which were offered privately to clients, have been over-subscribed.

PENSON v. LE COUTEUR.—In the Chancery Division of the High Court of Justice on Friday, the 19th, before Mr. Justice Byrne, Mr. Parker said he had a motion against Mr. Le Couteur, who was engaged in the photographic business, and he asked by the notice for three injunctions. On the present occasion he only asked for one injunction. The plaintiff formerly carried on business as the "Photographic Association," which he sold to a company, under the conditions of sale was that he should not carry on any business on his own account within five years of his ceasing to be the company as managing director. Mr. Druce, who appeared for the defendant, said he was willing to give an undertaking in terms of the third part of the notice of motion, which was as follows: "And also for an injunction to restrain the defendant, Wm. John Le Couteur, his partners, servants, and agents, until the said action or further order, from applying to any person who was a customer of the plaintiff's said business before April, 1899, the date as from which the same was sold by the defendant, Wm. John Le Couteur to the Photographic Association, limited, the predecessors in title of the plaintiff, privately, or personally, or by a traveller, asking such person to deal with the defendant, Wm. John Le Couteur or not to deal with the plaintiff." Mr. Parker said that the defendant ceased to become managing director, but he continued to serve as manager under a verbal agreement. There were certain ambiguous terms in the agreement, and the question might arise as to whether the agreement superseded the first, and, if so, could the plaintiffs get an injunction. What was proposed to be done was that the matter be set down, so that there might be a speedy trial. Mr. Druce asked for a fortnight in order to make preparations. Mr. Parker said ten days would be sufficient. Mr. Justice Byrne, however, would split the difference, and allow the parties twelve days. **Amusing Case.**—At the Clerkenwell County Court, on February 23, Thomas Gardner, tailor, 267, Liverpool Road, sued Percy Barnsbury Artistic Studio, Barnsbury Street, N., to recover in respect of alleged damage done to photographic negatives. Mr. Lewis, solicitor, appeared for defendant. Plaintiff said some time last summer, or the summer before, he was in the studio, he took a photograph of a wedding group and returned with the negative to execute a number of photographs. When they came home, after considerable delay, he found they were all spoilt. The Judge: In what way?—Plaintiff: There was a spot on each one as though he had been tampering with the negative. The Judge (examining the photographs) said they looked like a stray sunbeam. (Laughter.) Plaintiff added he had an order for two dozen photographs, but owing to bad weather he lost every order. Defendant said plaintiff asked him to return the negative, which he did, and agreed to print them for ten per dozen. He did eight of each negative within a week, and expressed his great satisfaction with them. After several unsuccessful applications for payment, he went to plaintiff's house and he hoped he was not going to treat him (defendant) as he treated other people. With that, plaintiff raised his crutch and threatened to strike him. Later on plaintiff came to him at a public hall and used such dreadful language that he had to go to a constable and have him removed. The Judge: We are asking the question of his language. Defendant: It was the first time ever heard. There was a religious meeting going on inside, and we were afraid of it being upset by his language. The Judge: A religious meeting was not going on at the time, was it?—Defendant: It was just over then. The Judge: What is the cause of the cloud setting over the head of one of the wedding party?—Defendant: I put it down to the plate not being properly washed and was first done. Plaintiff: I would like to say a word or two about the question of the religious meeting. The Judge: Never mind the religious meeting. If you used the language he said you used, it was time to have one in order to clear the atmosphere.

(Laughter.) Mr. Lewis pointed out that plaintiff was not clear as to whether the order was given last year or the summer before. And, further, he had not brought one witness or member of the wedding party to show that the photographs had been refused. The Judge said there was a small objection to the photographs owing to the spot or cloud, but this did not affect in any way the features of the group. As far as the printing was concerned, it was quite as well done as the copy itself, and the verdict would be in the defendant's favour on the claim. A counter-claim for 4s., the balance due for work done in connection with the order, was dismissed.

News and Notes.

A SECOND edition of Mr. Hector Maclean's "Popular Photographic Printing Processes" is in active preparation, and will be issued early in March by L. Upcott Gill, Bazaar Buildings, Drury Lane, W.C., under the amended title of "Photo Printing." The whole of the matter has been recast and the information brought up to date. The price of the book has been reduced from 2s. 6d. to 1s. net.

SOMETHING for Greenhouse Owners.—In Cowper's time greenhouses were the exception rather than the rule, and it is more than probable they did not cause their owners so much anxiety as those of the present day do. Anyway, the modern greenhouse owner finds by experience that his floral pets have many enemies, but his knowledge of natural history is not always sufficiently erudite to recognise them, or to know what steps to take to circumvent their mischievous exploits. "Amateur Gardening," in its issue of February 20th comes to his assistance, by providing him with a coloured-plate containing portraits of the chief greenhouse pests. Moreover, the journal also describes the peculiar vicious habits of each pest, and tells the reader the simplest and most effectual way of banishing it from the greenhouse, and thereby allowing his floral pets to grow and blossom without risk of injury to their subtle beauties. It appears that this is the first of a series of plates of garden pests and friends to be issued by our contemporary.

MR. THOS. SHARP writes to the "Morning Post":—"Your issue of the 13th inst. records the awarding of the Royal Astronomical Society's gold medal to Professor Hale 'for his method of photographing the solar surface and for other astronomical work.' Not for a moment do I wish to detract from Professor Hale's merits, but in common fairness I think attention should be drawn to an article by Mr. T. R. Dallmeyer in the 'Photographic Journal' of March 29th, 1895, entitled 'Inequality in Illumination in Photographic Lenses and De la Crouée's Remedy for the Defect,' in which it is shown that 'there is little risk in facing the light, and that the sun can be faced with impunity providing the lens is stepped down and made to fall upon the apex of the triangular figure produced in the ground glass.' Special attention is drawn by Mr. Dallmeyer to the value of M. De la Crouée's invention in astronomical and celestial work.

THE annual meeting of the Royal Astronomical Society was held at Burlington House last week. Mr. Choate, the United States Ambassador, attended to receive the Society's gold medal for presentation to Professor G. E. Hale. The medal had been awarded to Professor Hale 'for his method of photographing the solar surface and for other astronomical work.' Professor H. H. Turner presided. In awarding the medal he said that he did not intend to give a complete account of Professor Hale's work, but there were at least two important researches, independent of his work with the spectro-heliograph, which must be mentioned. The first was his determined search for some method of observing the corona without an eclipse. Hitherto it had been unsuccessful, but that was owing to the difficulty of the problem. Secondly, he must refer to the work done at the Yerkes Observatory from 1898 onwards in photographing the spectra of the fourth-type stars and measuring the photographs. In handing the medal to Mr. Choate, the President said: "Mr. Choate,—It is but three years since your Excellency did us the honour to attend our annual meeting to receive the medal on behalf of Professor Pickering. May I say that we

are in every way much pleased to see you here again. It will, I am sure, not lessen the value of this medal, which we ask you to send to Professor Hale as a token of the high value we set upon his work, if I add that it is also in some sort a symbol of our cordial admiration of the great advances made in our service by the astronomers of the United States and by the citizens of the United States, who have so generously aided their efforts." Mr. Choate, in receiving the medal, said that he considered it a very great honour to be asked to attend and to receive the medal, and would have much pleasure in transmitting it to Professor Hale. It was a medal the awarding of which was the crowning honour of any astronomer's work in the world. American astronomers enjoyed very rare facilities for prosecuting their work. They had 300 clear days and nights out of 365, and with that facility they certainly ought to do something. Public and private munificence also contributed very largely to their opportunities.

LANTERN SLIDES ON "BARNET" PLATES.

To the Editors.

Gentlemen,—We venture to send you at foot list of engagements during March for the lantern lecture on "Majorca" by Mr. G. E. Thompson, which is illustrated by fifty slides made upon "Barnet" Lantern Plates, especially with a view to demonstrating the wide range of colours obtainable by variations in their development. This lecture has been in circulation amongst the various photographic societies during the past few months, and its reception has been most gratifying, a very large number of appreciative letters having reached us regarding it.—We are, yours faithfully,

ILLICIT REPRODUCTION.

To the Editors.

Gentlemen,—In your last issue Mr. Turner, of Hull, reverts to a subject often discussed in your columns, namely, illicit reproduction of the photographer's work by copying firms and unfair newspaper competition. Their work is, as he says, inferior to the original maker's; but they "cut" the poorer class of bonâ fide photographer considerably. All this is true, and pity 'tis 'tis true. Will enclosed paragraph cut from an old copy of the "Photo Chronik" help them a little to gain their own:—

"As a guarantee against illicit reproduction the name of the photographer, or some design or mark, should be painted on the photograph in quinine sulphate, or some similar compound. It is not visible to the eye, but appears in black on a negative taken of it.

A mixture of water, glycerine, and a small quantity of fluorescein especially recommended for the purpose."

Being an amateur in a humble way, I do not know whether the above advice is known to many of the vast army of your readers give it as I received it.—Yours truly,

EDWARD D.
124, Osborn Road, Sparkbrook, Birmingham.

REMOVING SILVER STAINS FROM NEGATIVES

To the Editors.

Gentlemen,—Having noticed in the columns of "Answers to respondents," several queries as to silver stains on negatives, we have been experimenting in this direction for some time, and have discovered a formula with which we have been very successful, in removing stains from negatives, which were in such a state as to be entirely despaired of.

We should be pleased to give a practical proof of what we are able to do, if your correspondent would send a stained negative to us.—Yours faithfully,

JAS. HARGREAVES.
1, St. John's Buildings, Christchurch Road,
Boscombe (Bournemouth).
February 16th, 1904.

THE DECIMAL AND METRIC SYSTEMS.

To the Editors.

Gentlemen,—In a paper on "The Metric and Decimal Systems" published in this journal on February 12th, Mr. J. R. Gotz endeavored to convince us that decimals involve fewer figures than vulgar fractions and lend themselves more readily to multiplication; in proof of which idea he suggests a simple problem that most emphatically proves the contrary. It is far easier to multiply $6\frac{1}{2}$ by $4\frac{1}{2}$ than 6.5 by 4.75 , because the result is apparent in the first case and not in the other. Any person practically skilled in the use of figures would at once mentally convert the decimals into fractions, knowing that the result could be seen without any working out on paper. The fractions would be used in the incomprehensible fashion described by Mr. Gotz, yet in the authorised manner of the arithmetic books. They would be worked by cross multiplication, or, perhaps, by a method founded on some algebraical formula. The user would have several methods available, and would instinctively use the shortest one. In the majority of cases decimals representing simple fractions are best worked as fractions, for if you write in decimals and think in fractions the result can generally be written straight down. Even whole numbers are often best treated by inserting a decimal point and converting the result into a vulgar fraction, when your product or "square" is once apparent. For example; $1225 \times 1.225 = 1225 \times \frac{1225}{1000} = 1225 \times \frac{1225}{1000}$ all be squared without any working out by simply writing in decimals the square of $12\frac{1}{2}$ and then shifting the decimal point to the place. I wonder if Mr. Gotz would multiply out to find the square of 21.142857 , or of 12.083 , or the product of $.3$ by $.6$, or of $.142857$, or of 931.7861 by 333.3 . (He should solve all five within a minute and a half.)

If, instead of speaking of the "incubus" of the vulgar fraction, Mr. Gotz had pointed out that fractions were often necessary to the advantageous use of decimals, he would have shown much more practical knowledge of his subject.

The great defects of purely decimal systems are that they do not lend themselves to the quick calculation essential in the business world. That they seldom show obvious results; that they frequently require the use of surplus and unnecessary figures to arrive at small exact results; that repeaters constantly lead to confusion and wholly unnecessary complications; and that decimal points and repeater points get into the wrong places. It is generally necessary to use decimals and fractions together to save the time and work that is of pecuniary value in the practical world.

It is remarkable that Mr. Gotz should be of opinion that a duodecimal system has advantages when he only considers the fanciful question of duodecimal notation. He ignores the fact that we have in common use a most invaluable duodecimal system, by which we can count squares in feet and inches in far less time than is possible with the metric system. We can multiply, say, $12\text{ft. } 7\frac{1}{2}\text{in.}$ by $4\text{ft. } 9\text{in.}$ more quickly than the corresponding dimensions of 3.848m. by 1.401m. for the former sum only requires a maximum of six working figures.

the latter needs twenty-seven figures and at least thrice the time—seconds against fifteen seconds—according to a rough trial. The defects of the metric system are very obvious to all who are acquainted with it and with the sundry English systems. First, series only of units, all increasing in geometrical progression, is inefficient, for practical experience shows that units must be varied for secure economy. It is not practically possible to devise any one series of uniform ratio that will fit all requirements. Again, the fact that the metric system acknowledges only decimals is a serious defect, as I have endeavoured to point out, decimals are most seriously inconvenient in a variety of cases. Then, again, there is the worst defect of all, which is the lack of economically efficient units. The new fashion in which the length of the metre was fixed has spoilt the system, for even that unit is slightly too long, though it is the best of all the metric units. As Mr. Gotz seems to consider the exact length of the metre to be of little consequence, it is evident he does not appreciate the advantages of economical units. It is, however, a curious fact that if for any particular purpose you use a unit that is either longer or shorter than it should be, you suffer a loss of time, energy, or efficiency; possibly in all three. We have now in use in England two decimal systems that are far superior to the metric system, one being the system of land measurement with the almost perfect economical unit of the chain, and the other the system of small parts of an inch used for small measurements, which contains a good economical unit of the inch, the hundredth of an inch, and the thousandth of an inch. The small units of the metric system cannot compare with these. To expand this system by adding new units of 100, 1000ths, etc., would be of no use, for we should then lose our valuable duodecimal system and only gain a series of uneconomical units. Our linear units are fairly good as they stand, and though our measures generally have many defects and require reform we do not want decimals introduced everywhere, nor do we want to measure all commodities by the same units. A perfect system would be a very simple one, not an academic compilation, including useless units put in for no other purpose than that of filling up a pedantic series, and containing a large number of units of real value.—Yours, etc.,

C. WELBORNE PIPER.

February 17th, 1904.

LADIES' FIGURES.

To the Editors.

Gentlemen,—According to the daily papers about sixty ladies and many more gentlemen have joined the Anti-Corset League at Leeds. The league is an off-shoot of the Leeds Society of Physical Culture. The male members of the league have, it is said, vowed not to marry "Corset Wrecks," and the ladies are exhorted, at peril of excommunication from the society, to abandon the use of corsets entirely, and there is a hard and fast rule that every male member shall have no restriction bands or other light things round the waist. If the Anti-Corset League are successful in bringing about a revolution in feminine fashions—and figures—there should be good for professional portraitists. Ladies always want portraits in the most fashionable attire, and if corsets were abandoned they would no longer tolerate their portraits with their faces "trussed" up as they sometimes are by this unseen garment, which renders them anything but a model of the *Venus di Medici*. At the present fashion rules, and I think that it will take some time before any leagues will displace it. If it were displaced, it is questionable if photographers would be quite so successful with any of their lady sitters as they are at present, or, at least, give equal satisfaction to them. However, the revolution is not yet at hand, and it is doubtful if the corset-makers are very much disconcerted about what the anti-corset leagues are doing.—Yours, etc.,

APOLLO.

LIVERPOOL Amateur Photographic Association.—At a Council meeting recently, it was resolved that, with a view to presenting the secretary, Mr. Simmett, with a suitable memento of his term of office, a subscription list be opened, and that the members of the association be requested to intimate their willingness to subscribe. The maximum subscription has been fixed at 5s., but smaller sums will be welcomed, as the Council naturally wish the subscription list to be a thoroughly representative one.

Answers to Correspondents.

- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. Bell, 19, Canal Street, Heywood. Photograph of E. H. Holden.
- J. C. H. Balmain, 69, Shandwick Place, Edinburgh. Three Photographs of Miss A. Russon as "Cinderella."
- D. Ross, Norman Place, Leslie, Fifeshire. Three Photographs of the Dule Tree on Lyle Green.
- J. A. Horsburgh, 4, West Maitland Street, Edinburgh. Photograph of the late Dr. R. M. Murray.
- L. Anthony, 2, High Street, Killarney. Three Photographs of "The Killarney Colleen."
- E. W. H. Butler, 117A, High Street, Croydon. Photograph of Group of Eight Clergymen.
- H. J. Comley, 10, Russell Street, Stroud. Photograph of W. B. Stewart.

DRAWINGS REGISTERED:—

- J. S. H. Bates, 13, Evington Street, Leicester. Two Drawings for Booklet Covers.
- W. H. REYNOLDS.—We have no fuller address than that we gave you in our previous answer.

ENLARGEMENT (Uddingston).—The enlarger, mentioned in your letter, is a very good one for the money, and excellent results may be obtained with it.

REGISTRATION OF COPYRIGHT.—R. J. CROSBY says: "I have a portrait of a gentleman that I want to have registered. I am informed you undertake to see to registering. Will you kindly say what I shall send re prints and fees; by so doing you will do me a great favour?" In reply: If you send us two copies of the portrait, and one shilling and sevenpence in stamps, we will effect the registration for you.

BOOK WANTED.—"BLACK AND WHITE" writes: "Would you be so good as to recommend me a reliable text book on 'black and white' for pen and ink work; especially such as is required for paper or magazine illustrating? I do not wish for an elementary book on pen and ink drawing, but in black and white for process reproduction." In reply: "Hints on Drawing for Process Reproduction," by C. J. Vine. It may be obtained through any of the dealers.

STRENGTHENING ALCOHOL.—W. A. WILSON asks: "Will you kindly tell me in which edition of the ALMANAC or number of the Journal I shall find the recipe for getting water away from methylated spirit? I believe I have seen it, but cannot turn it up at present." In reply: Shake the spirit up with some welldried and powdered carbonate of potash. That will absorb the water and sink to the bottom of the bottle when the spirit can be decanted off.

COLOURING.—H. R. HOGGEN says: "Kindly inform me which is the best preparation to use as a smooth coating previous to colouring photos, its composition, mode of use, and treatment in making up before using?" In reply: You do not say the sort of paper you have to deal with, or kind of colouring. As a rule no coating is required. If the paper is repellent of the colour a slight wash of prepared ox gall, as sold by artist's colourmen, may be applied, or the surface of the print may be rubbed over with a piece of pencil eraser.

FLIES IN WINDOW.—"TORMENTED" asks: "Can you enlighten us as to any means of keeping flies out of shop window?" In answer: This query in no way relates to photography. But as you are a firm of professional photographers we reply. If you have an inner casement fitted to the window, such as

is usual in shops where fancy and delicate things are shown for sale the flies will not be able to get in the window if the casement is kept shut. An alternative plan would be to catch the flies as they enter the shop and kill them at once.

BURNISHING UNMOUNTED PRINTS.—"BURNISHER" says: "I have just bought a new globe enameller, and my work being mostly for publication the prints are unmounted. Now the difficulty is, I cannot put them through this class of burnisher because it creases the prints. Have tried cardboard (thick and thin), also blotting paper, etc., without success. Can you suggest anything, or must the burnisher be a flat one for rolling unmounted prints?" In reply: Burnishers are not well suited for unmounted prints. They are best dealt with in a rolling press provided with a polished steel plate.

PHOTOGRAPHIC PAINTINGS.—"PAINTER" asks: "Could you kindly inform me of the correct plates and colour filter to use for photographing oil paintings (sea and sky chiefly) to produce such results as are obtained in the Royal Academy 'Pictures of the year,' etc.?" In reply: All the plate makers supply orthochromatic plates, and many of them light filters to use with them. But it is against our rule to recommend any particular maker's goods. You must keep in mind that the reproductions you refer to are produced by photographers who are highly skilled in that class of work, and also that as much depends upon skill as plates.

COLOURED LIGHT.—"LIME LIGHT" asks: "Would you kindly inform me how to make the different coloured tinters, viz., crimson, blue, green, amber, mauve, pink, etc. as used in theatrical lime boxes? I don't mean the ordinary coloured glass, as it is too dense; but some sort of stain that is used, like coating a glass with coloured collodion and binding like a lantern slide. (1) What vehicle is used to hold the colour? (2) How are the various colours made and with what substance?" In reply: (1) We have had no personal experience in this kind of work, but we should think that glass plates coated with gelatine and then dyed with coal-tar colours would answer. An unexposed and fixed dry plate would probably answer. (2) Judson's dyes would be suitable.

BLINDS FOR STUDIO.—"BLINDS" writes as under: "If you would kindly answer the following questions I should feel greatly obliged: (1) What would be most suitable for blinds and colour of same for the studio of which I send you sketch with dimensions? (2) What is the most suitable colour for paint and paper for the walls of studio? (3) After spring rollers (which I am afraid I cannot afford) what is the most efficient system for fixing and working blinds?" In reply: (1) A light green window Holland would be very suitable. (2) Any light tint, say a French grey or other colour that will accord with the surroundings. (3) Spring blinds would be the best. But cords and pulleys, such as are used for window blinds, can be employed.

FEES FOR REPRODUCTION.—"W. H. DEE" asks: "Can you kindly inform me what the usual charges are for cabinet photos with right to reproduce. I have never taken less than 5s. for cabinet and 10s. 6d. or 21s. for 8½ by 6½ or 12 by 10 groups. But enclosed you will find copy of letter from Manchester, stating my charges are extremely excessive, and as I do a fair amount of work with papers I shall be glad if you can answer what the usual charges are?" In reply: The usual fee, to a newspaper, is 10s. 6d. for sizes up to cabinet, and larger sizes in proportion. What you have been charging are only about half those suggested by the Professional Photographers' Association. See pages 977-80 of the "Almanac." The prices offered by the Manchester house are ridiculous.

ELECTRIC LIGHT.—"ELECTRIC" writes: "Will you kindly oblige by answering the following questions: (1) Who are the makers of portable studio electric lamps? (2) What would likely be the exposure with one of these lamps, using same lens, stop, and plate which would give a fully exposed negative at three seconds ordinary daylight in studio? (3) What would be the distance required for vignette head, three-quarter, and full

length figure; that is, how far would the lamp require to be distant from the subject? In reply: Messrs. W. M. Still & Co., 24, Charles-street, Hatton-garden, makers of the Addison light. (2) Depends upon which size apparatus you employ. (3) This depends upon the lighting required. Better write the Messrs. Still for a prospectus. We do not answer queries by post.

METOL TROUBLES.—"E. J. Sander" says: "I shall be glad of advice on the following subject: 'My thumb and first and second fingers of right hand have started to dry up, and the skin to crack and open, not very badly, but sufficiently to have to keep them covered with rubber finger stalls. I am inclined to think it is due to the use of the Velox acid fixing bath. I have lately taken to making it up, and have only lately got the skin trouble. I have used metol, quinol developer for a long time, but much more frequently lately, and I am certain to which to attribute it. Any advice or treatment you can give me I shall be glad to adopt, as I am very loath to give up either the acid fixing bath or the metol quinol developer.'" In reply: There is very little doubt that the trouble is due to the metol and to nothing else. If you relinquish its use we have no doubt but that your fingers will get all right. If they do not, better consult a medical man.

LENS QUERIES.—"STUDIO" says: "I am building a small studio rear of house, and should like your advice. Owing to lack of space it is only 16 ft. in length, 9 ft. wide, 8 ft. to eaves, 11 ft. to highest part of roof. It is being built along brick wall, as shown in sketch enclosed, which rises above roof 6 feet, cutting off a good deal of top light, though side light is unobstructed. As length of studio will not permit use of long focus lenses, I am thinking of using a Busch 7 in. f6 Portrait Aplanat F 6 for full length figures, and same perhaps 11 in. focus for bust. What I should like to know is: Would the lenses named at F 6 and using the new rapid series of plates be fast enough; (2) would the focal length be sufficient to prevent distortion; (3) would the light be improved by whitewashing wall obstructing top light; (4) as only one end of studio would be used, how much light should be blocked at sitter's end, and how much top and side light should be given; (5) what colour blinds would you advise?" In reply: (1) Yes, for general purposes. (2) Yes, fairly so, unless they are brought very near to the sitter. (3) Not material, not worth the trouble. (4) About four feet. (5) As to aspect of the studio is not stated, we cannot say what colour would be best.

We have received from Messrs. H. Poths and Co., of 4, Bury Court, St. Mary Axe, London, E.C., a thirty-six page catalogue of specimens and show bottles for exhibitions, museum collections, etc.; also sample bottles, cardboard boxes, and sample bags. A copy of the list may be had on application to Messrs. Poths.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

tical Much has been said during the recent
ISS. fiscal controversy concerning the loss this
country has sustained by the importation of optical glasses
in Germany, but to whichever political party those who
present the fact may belong, they must admit that the great
damage Germany has made in the manufacture of this
material is due to the perseverance and skill of two men,
who were brought together by a happy chain of circum-
stances. But orators and partisans are guilty of much
aggravation with regard to the commercial importance of
this article, as may be seen from the following statistics,
taken from the German paper "Photographische Indus-
trie." It appears, from the official returns, that Germany
imported M624,000 (about £31,200) worth in 1902 and
M74,000 (about £28,700) worth in 1903. On the other
hand, Germany imported optical glass in 1902 of the value
M233,000 (about £11,605), and in 1903 of the value of
M204,000 (about £10,200). It may be gathered from these
figures that Germany, like Great Britain, does not produce
the optical glass it uses, and it must derive some advan-
tage either in price or quality, from that which it imports.
From the fact that the quantity is proportionate to the
value in each case, it may be inferred that the optical
industry has suffered considerable depression during the
last year. In turning to optical instruments, including
photographic apparatus, we find remarkable confirmation of
this German loss of trade. In 1902 the exports amounted
to £665,200, but last year they fell to £444,600, the greatest
decline being in the trade with Belgium, France, and Great
Britain. The imports into Germany have not declined

much, being £27,050 in 1902, against £23,200 in 1903. These figures not only show that the foreign trade has declined very considerably, but that the market in Germany for foreign-made instruments, etc., has not suffered to anything like the same extent. Some explanation of these facts would be very interesting.

Tilting the Lens.

The Austrian Photographic Association, with commendable enterprise, have recently started the publication of a photographic newspaper, which is called the "Oesterreichische Photographin Zeitung." We send the Association our best wishes for success in their new venture. We cannot, however, refrain from adversely criticising one of the methods mentioned by Herr Max Jaffé in an article entitled "Some Photographic Dodges." As one means of curing distortion he mentions the tilting of the lens, taking care that the focussing screen be perfectly upright. The recommendation is a sound one so far as the screen is concerned, but why tilt the lens? Herr Jaffé is careful to point out that the definition will suffer considerably at the top and bottom of the picture when the focus is adjusted for the centre, and he recommends the use of a very small stop, measuring about $f/1000$, to obtain tolerable marginal sharpness. Did Herr Jaffé ever try the method? We suppose the tilting of the lens is advised for reducing the foreground and including the upper part of the building, or other object, it may be desired to photograph; but will tilting the lens help much? One of the devices for finding the optical centre of a lens is to place it on a block of wood pivoted at its centre, when, by rocking and sliding the lens backwards or forwards, a point may be found at which the image is quite stationary. But the lateral movement near that point is not much, and of little or no value for the purpose indicated. Perhaps the diameter of the stop, through a printer's error, may be incorrectly given, but if the author was guilty of this indiscretion he will find, by working out the comparative exposures, taking 1.5 sec. for $f/16$, that the lens must remain uncapped for at least 13 minutes for $f/1000$. Even then no allowance is made for diffraction and the inertia of the plate. In the illustration showing how the lens may be tilted we notice that the screw by which the camera front may be swivelled and clamped in position runs in a groove, which would permit of raising of the lens to a considerable extent. Were the lens raised a little the effect could be obtained without destruction of definition and the use of an absurdly small stop.

* * *

A Weather Plant.

A few plants about a studio are always useful, and, properly disposed, ornamental; but if among them there were included one capable of prognosticating the weather their

usefulness would be increased manifoldly. Recently, at the Society of Arts, Baron Fridland described such a plant in his lecture, "Forecasting of Atmospheric and Seismic Disturbances on Land and Sea." Fortunately, we do not in this country, at any rate, as they do in Japan, for instance, want to know much beforehand about earthquakes, though we have heard such a description given of the results of a careless printer having broken a valuable negative; but if we could have a plant in the studio or reception-room capable of telling us what the weather was going to be like for the next day or two its advantages would need no argument to prove. The *Abrus Precatorius Nobilis* is the name of this wonderful vegetable product, which, with suitable precautions, can be grown by anyone, the lecturer stated. According to variations in the distribution of the electric and magnetic forces of the atmosphere of the earth which takes place, the plant performs peculiar and abnormal movements, each having its definite signification, a knowledge of the meaning of which enables the observer to predict the weather almost a month in advance. From a single station—say London—he could, said the Baron, issue special charts 24 to 28 days in advance showing the "critical" barometrical centres, the atmospheric and seismic disturbances, and signs of fire-damp explosions that might result therefrom; issue daily charts, showing from two to seven days in advance the lines of equal barometrical pressure; and, most important of all to photographers, the districts of rainy, fine, and foggy weather; and, finally, to publish daily a detailed forecast, 48 to 72 hours in advance of the weather, within a radius of from 40 to 60 miles. Lest every reader should at once rush to purchase an *Abrus*, we have to add that the lecturer stated that, though almost anyone could grow the plant, it was impossible to interpret its indications without a great deal of training and subsidiary knowledge. The vast importance that a knowledge of how to successfully forecast the weather would be to photographers needs no discussion, and it cannot be doubted that already the public forecasts given are less untrustworthy now than they were a number of years ago. Many new facts are discovered which go towards perfecting the system of forecasts, many old notions are exploded, and some resuscitated. Most interesting among the latter is one dealt with by Mr. H. C. Russell, the Government Astronomer of New South Wales. The old popular notion of the moon's influence upon the weather has long been scouted by all scientific men, yet Mr. Russell states that he has discovered, to his own satisfaction, that the rainfall is governed by the moon, and he gives a diagram showing that when the moon's course is to the southward, in the southern hemisphere at any rate, more rain falls than when the moon moves to the northward.

* * *

Incandescent Electric Lamps and the Osmium Lamp. Users of incandescent electric lights in the studio have a fair experience of the cost of glow-lamps, and their gradually diminishing efficiency as their age increases, and everyone is familiar with the blackening of the interior of the bulb that gradually takes place, though sufficient attention is not commonly given to its concomitant phenomena. The blackening is accompanied by a very serious decrease in power, and especially for photographic purposes, thus: the discolouration naturally absorbs some light; as it arises from particles of the filament being thrown off, the filament being altered, and its emissivity for heat increased, its temperature, *ceteris paribus*, is consequently decreased, its light diminished in intensity, and, naturally, in actinic power, which also suffers still further through the thinning of the filament increasing the resistance, with consequent passage of less current and fur-

ther diminution of intensity of light. We would direct particular attention to this latter feature. The photographic power of the glow-lamp diminishes far more than the illuminating; as the brightness of an arc lamp is raised, the greater the photographic efficiency. This is well shown by the fact that it is possible so to reduce the intensity as, for example, in running several lamps in series—that a suitable dark-room light will be produced, sufficient to read by, for example, but insufficient to fog a plate unless by long exposure. The "life" of the lamps is variously estimated at from 800 to 1,000 hours; but long before that time has passed the wise photographer will have smashed and replaced them. It seems a pity that a spent lamp cannot be utilised again, but, so far as we are aware, there is no market for them when worn out. Such being the case, any promise of a lamp with a longer life of efficiency will be examined with interest, and this appears to be the case with the Osmium lamp, a short account of which, by Professor F. G. Baily, recently appeared in the "Electrician." It consumes rather less current than the ordinary carbon filament—1.9 watts, as against 2.1 watts, per candle—the colour being practically the same as carbon. This would mean a diminution of about 10 per cent. in the bill for electricity; but that is not all, for Professor Baily considers that the main cause of the higher efficiency is the greater temperature which the Osmium filament can stand, and this, as we have just pointed out, means higher photographic power. It appears the only trustworthy life tests available are those of Professor Wedding, who, testing eighteen lamps, proved their life to be on an average about 1,900 hours—perhaps twice that of the carbon lamp. The diminution of luminous power worked out at 20 per cent. at the end of the trial compared with their power at the start. The drawback at present seems to be the inability to produce a high voltage lamp, 55 volts being the highest p.d. for which at present they are manufactured.

THE OLD PHOTOGRAPHY AND THE NEW.

At the conclusion of a previous article on the above topic (see page 123 *ante*), in which the difference in the principle involved is the production of negatives prior to the introduction of gelatine emulsion photography, with regard to the probable stability of the results, was treated upon, we intimated that we might revert to the question with reference to prints. No one will dispute the fact that a very large proportion of the silver prints made, say, during the past decade or so, show a marked lack of stability, while many may be seen in old family albums that were made some thirty or forty years ago which are practically unchanged, and some even as good as when first produced. Prints, it is true, were made in the early days of the art that have not withstood the test of time, but it would be safe to say that a proportionately far larger number of silver prints produced now show earlier signs of decay than did those of thirty or forty years ago.

We shall here point out, as we did with regard to negatives, the different conditions under which the earlier prints were produced and those obtaining now. We refer particularly to printing-out processes, as the development ones were dealt with in connection with paper negatives. Up to the time of the introduction of gelatine papers, albumenised paper was the one in vogue. Going back to the earliest days of its use, we are reminded that what was then termed albumen paper was what would now be called a matt surface one, inasmuch as the albumen employed was largely diluted with water.

If we refer to the third edition of "Hardwick's Photographic Chemistry" (1856), we find the formula for this

paper stands thus:—Chloride of ammonia, or chloride of sodium, 200 grains; water, 10 ounces; albumen, 10 ounces—that is, equal parts of water and albumen, with 10 grains of chloride to each ounce. On this the paper, which was of a thinner and purer kind than is necessary for gelatine O.P.'s, was floated for a minute and a half. When dried it was sensitised by floating it on plain solution of nitrate of silver, 60 grains to the ounce of water, for three minutes. A much stronger solution than this used to be frequently employed. Here, it will be seen, the chloride of silver as formed by a double decomposition. Now it will easily be realised that the albumen and the chloride, with the one and a half minute floating, would penetrate well into the body of the paper, and with the three minutes on the silver bath the solution would soak deeply into the paper, and could, also, have much remaining on its surface when dried. As a consequence, the image, when printed, was as much in the body of the paper as it was on the surface. But this was not all, for the negatives in vogue then were totally different from those of the present time. They were collodion ones, having great density in the lights, and perfectly clear glass for the deepest shadows. They took a long time to print, and, as a consequence, they were deeply frozen in the shadows, and the image was well in the body of the paper, and with specially strong negatives it showed strongly on the back, proving that the image was composed of a large quantity of reduced silver.

At the time referred to the toning bath employed was the combined one. It was very strong, and contained only gold, with sometimes a little silver, hypo, and water. No such things as alum, lead, acid, etc., were used as in the modern combined bath. We have said that the bath was very strong. Here is the formula as given in the edition of Hardwich just quoted from:—Chloride of gold, 4 grains; nitrate of silver, 16 grains; hyposulphite of soda, 4 ounces; water, 8 ounces. The toning took a tolerably long time, usually from a quarter to half an hour, and frequently much longer, as the gold became exhausted, so that there was little question as to whether the pictures were fixed or not. Notwithstanding that, some workers further fixed the prints by an immersion of ten minutes in a fresh solution of hypo. With plain salted paper, which at that period was largely used, similar conditions obtained; the paper was heavily salted, and was sensitised in a strong solution of silver—either the ammonia-nitrate or plain nitrate.

At a later period the albumen was less diluted. Hardwich (1861 edition) gives the proportions:—Albumen, 15 ounces; water, 5 ounces; the chloride remaining as above. When the *carte de visite* became the rage a more glossy surface was desired, and then the albumen was employed undiluted, and sometimes thickened up by evaporation. In this way the image was kept more in the albumen coating; still, much of it was in the paper itself. About this period a separate toning and fixing system was generally adopted, which, theoretically, added to the stability of the picture. The prints, after fixing, were washed in cold, and afterwards in warm water, and at the later stages in quite hot, so as to ensure the removal of the last traces of the hypo.

Having referred pretty fully to the old conditions, let us consider those now prevailing. With the gelatine O.P.'s, the paper is usually surfaced with a "baryta" substratum, on which the emulsion is spread. The chloride of silver is formed in the emulsion, and not, as in the former method, by double decomposition in the albumen and the paper; it also contains an organic salt to add vigour to the image, and very little free nitrate of silver. The negatives now used are very unlike in character those employed in the old days, being feeble in contrast as compared with them. In the modern prints the image is con-

fined entirely to the gelatine, whereas it used to be to a great extent in the body of the paper itself, as could be seen if a print were roughly torn across.

There is another process that should be referred to here, as it of late has come under suspicion as regards stability—namely, the collodio-chloride. This process should, theoretically, be the most permanent of all silver processes, and it has proved itself to be so when worked under the old conditions. In its early days the paper used was the same as that used for albumenising, which is the purest photographic paper made. It was first given a thin coating of arrowroot, and, after drying, the collodion emulsion was applied. In the modern collodio-chloride process a cheaper paper is used, and it is surfaced with a "baryta" coating similar to that for gelatine papers, and there is very little question that the free nitrate in the emulsion to an extent combines with the vehicle with which the "baryta" is cemented to the paper. Hence it will be seen that there is a considerable difference between the collodion paper of thirty or forty years ago and that at present on the market.

We think we have now pointed out, both with regard to negatives and prints, the difference between the principles involved in the early methods and the more modern ones. This we have endeavoured to do in such a way that the subject may be well understood by those whose experience in the art has been confined to the last decade or so, and with gelatine emulsion photography only.

CURIOUS OPTICAL ILLUSIONS.

[From *Popular Astronomy*.]

AMONG the various phenomena of nature that occur unpredicted and unannounced to mankind, there are few more interesting to scientific students, and probably none so deceptive and commonly misunderstood by the general public, as the luminous coloured circles occasionally seen around the sun, and more frequently around the moon, known respectively as the solar and lunar halo. These remarkable exhibitions of Nature, owing to the complicated appearances they sometimes present, have long engaged the attention of meteorologists, and were, until within a comparatively recent time, extremely difficult to explain. Though more frequently observed in the polar regions, there are probably few persons of mature age, residing in the temperate latitudes, who have not, at some period of their lives, witnessed one or more exhibitions of these curious and beautiful phenomena, which, perhaps more than any other manifestations of nature, have engaged the observation of the unscientific world, and attracted multitudes of thinking people to the study of physical science, particularly that fascinating department pertaining to the atmosphere.

There are probably no displays of Nature, either in the heavens or the earth, about which the people are so misinformed, and regarding which so many erroneous notions seem to prevail, as the occurrence of solar and lunar halos, together with the anomalous appearances usually presented by them, though the amount of ignorance relative to these wonderful exhibitions is not surprising when we consider their puzzling nature, and the deceptive features that invariably accompany them, which at one time the wisest philosophers were unable to correctly interpret and explain.

Whenever, under favourable conditions, we observe a luminous circle of the various prismatic colours around the moon, the sky within the circle being much darker apparently than it is upon the outside (which is the peculiar feature of a lunar halo) an observer is very naturally led to believe that a ring of light does actually surround the moon's disc, while inside the ring there is but little, if any, light at all, the sky being dark and unilluminated, and that portion just outside really much

brighter, though less bright than the ring itself. Now, it is in this belief that we are deceived by appearances, and that the perplexing nature of a halo is well illustrated; and yet people will claim, "as seeing is believing," they have an ocular demonstration that a real luminous circle does surround the moon, and that the dark sky inside receives no light from the moon's disc, being actually without any illumination, as it appears to be. But paradoxical as it may seem, it is nevertheless a fact that the sky is really no brighter where the circle of light appears than it is anywhere else around the moon, and only seems to be for the reason that owing to the refraction of the moon's light at an equal distance from her disc, on all sides, more of the luminous rays reach our eyes from the portion of the sky where the circle or ring is seen.

That there is no real luminous circle around the moon, and that the sky is equally bright where it appears the darkest—the whole appearance being deceptive, as above stated—will be manifest when the cause and nature of the singular phenomenon are fully understood. The late Professor Proctor, explaining similar phenomena in a very interesting and instructive newspaper article entitled "Seeing is Deceiving," well remarked: "'Seeing is believing,' says the old proverb, but 'seeing is deceiving' would be nearer the mark. We are deceived almost as often, perhaps quite as often as not, by what we see. We are deceived by false impressions even when we know the real state of the case, so that Nature may in some sense be compared with a conjuror who explains the trick he is about to play, yet deceives the eye as perfectly as though we knew nothing about the manner of his performance. We know that that handkerchief which we gave him to experiment upon has not been cut in half, yet we saw him cut it in half; we know he has not pounded our gold watch with a mortar, yet that is what we saw him do."

The lunar halo, which by many persons is regarded as a remarkable and unexplained luminosity associated with the moon, is to meteorological students neither a mysterious nor an anomalous occurrence. It has been frequently observed, and for many years thoroughly understood, and at the present time admits of an easy scientific explanation. It is an atmospheric exhibition due to the refraction and dispersion of the moon's light through very minute ice-crystals floating at great elevations above the earth, and is explained by the science of meteorology, to which it properly belongs; for it is not of cosmical origin, and in no way pertains to astronomy, as most persons suppose, except as it depends upon the moon, whose light, passing through the atmosphere, produces the luminous halo, which, as will be seen, is simply an optical illusion, originating, not in the vicinity of the moon—two hundred and forty thousand miles away—but just above the earth's surface, and within the aqueous envelope that surrounds it on all sides.

A lunar halo, or circles of prismatic colours, seen around the moon, never occurs except when the sky is somewhat hazy, and presents a dull, leaden appearance. Usually only one circle is seen surrounding the moon, and it is always of large size, being about forty-five degrees in diameter, or eighty times the apparent diameter of the moon, corresponding to one-half the distance from the zenith to the horizon. The sky within the circle is always apparently much darker than it is for some distance on the outside—a feature which is the peculiar characteristic of a halo when seen under the most favourable conditions—and the circle exhibits the seven prismatic colours seen in the rainbow, and the inner edge being red, and quite sharply defined, while the other colours are more or less mingled and superposed, so that the outer edge of the circle is nearly white, and usually not very clearly defined.

Sometimes a number of large circles are seen around the moon, presenting a peculiar and very complicated appearance, and they are seldom concentric as in a lunar corona, but intersect each other with mathematical exactness, exhibiting a struc-

ture that is often wonderful to behold. A true halo is never produced when the sky is perfectly clear, as a slight haze is essential to its appearance, and the beautiful illusion is visible only under rare and peculiar atmospheric conditions. In connection with the halo, white bands, crosses or arches, are sometimes observed, which also result from the same conditions in the atmosphere at great elevations above the earth.

A halo may form around the sun as well as around the moon, and all the curious features above described are similarly observed; but a halo is most frequently noticed about the moon for the reason that we are too much dazzled by the sun's light to distinguish faint colours surrounding its disc, and to see them it is necessary to look through smoked glass or view the sun by reflection from the surface of still water, by which means its brilliancy is very much reduced. When a halo is seen around the sun, a white circle passing through the sun and parallel to the horizon is sometimes observed, which is known to meteorologists as the "parhelic circle," from the fact that parhelia or mock-suns are frequently noticed in connection with it. These productions, which are commonly called "sun-dogs," are faint images of that luminary, appearing at one, two, or more points in connection with a halo, and at those parts where the circles cross each other, or cut the parhelic circle above mentioned. The number of these mock-suns, or parhelia, visible at the same time, is variable; sometimes one or two only are to be seen, at other times four or five, and on some occasions as many as seven have been observed at once. These mock-suns usually appear about the size of the real sun, but not quite so bright, though on rare occasions they are said to rival their parent luminary in brilliancy and splendour.

Such appearances, which are also seen about the moon (known as mock-moons or "moon-dogs") are most frequently observed in the polar regions, but often occur in the more temperate latitudes, and are produced by the extra light concentrating at those points where the circles intersect, there being at such places a double cause of illumination, presenting the singular spectacle of a faint white disc, resembling that of the sun or moon. Parhelia, or mock-suns, are generally red on the side toward the sun, and they sometimes have a prolongation in the form of a tail, several degrees in length, which coincides in direction with that of the parhelic or horizontal circle. A recent writer on the subject says: "Parhelia have been observed frequently both in ancient and modern times. Aristotle records two appearances of these meteors, and Pliny mentions their occurrence at Rome. A double parheliion, which was noticed before the Christian era, is referred to by St. Augustine. Many others have been observed from different points of the Continent. On January 2nd, 1586, Christopher Rotham saw at Cassel, before sunrise, an upright column of light of the breadth of the sun's disc. As he rose to view he was preceded and followed by a parheliion, which appeared in contact with his orb, and continued visible for thirty minutes, and then was hidden by a cloud. On February 28th, 1551, mock-suns were seen at Antwerp; and on March 17th of the same year a similar phenomenon, with two halos, was witnessed at the same place. Four days after the last-named two parhelia, with three halos, were seen at Madgeberg."

A halo may be produced artificially, and its appearance beautifully illustrated, by crystallising some salt (such as alum) upon a glass plate, and then looking through the plate at the sun or a bright light, then the luminous circles above described will be observed. The formation of a circle of light around the sun or moon, and the production of the dark circle to which we have referred, may also be illustrated by an interesting imaginary experiment, which is thus described by the late Professor Loomis, an eminent authority on the subject of atmospheric phenomena: "If we conceive a beam of light to be admitted through a small aperture into a dark room, and

to fall upon a large number of ice-prisms having angles of sixty degrees, and occupying every possible position, all the incident rays will be deviated from their first direction, but in no case will the deviation be less than about twenty-two degrees. A large number of spectra will be cast upon the opposite wall, but opposite to the aperture through which the light is admitted there will be a circle of twenty-two degrees radius upon which no spectrum can fall, and the red end of each spectrum will be turned toward the centre of the circle. If the number of the spectra be sufficiently great, they will together form a circle of twenty-two degrees radius, bordered with the red on the inside; but beyond the red the different colours will be so superposed as to produce a light nearly white. . . . The circle within the halo is much darker than the space without it, because from no part of this circle can a ray of the sun, refracted by the ice-prisms, reach the eye of the observer."

The halo is less brilliant and beautiful, but far more frequent, than the rainbow. Scarcely a week passes during the whole year in which the exhibition does not occur. In summer the ice-crystals that produce the halo are three or four miles high, above the limit of perpetual frost, and for this reason the exhibition is sometimes called the "frost-bow." As the rainbow is sometimes seen in dew-drops on the ground, so the "frost-bow," just after sunrise, has been noticed in the crystals which fringe the grass. A halo is the bright border of an illuminated zone; and Professor Olmsted says: "As in the rainbow, so in the halo, the visible band of colours is the only border of a large illuminated space on the sky. The ordinary halo, therefore, is the bright inner border of a zone, which is more than twenty degrees wide. The whole zone, except the inner edge, is too faint to be generally noticed, though it is perceptibly more luminous than the space between the halo and the luminary."

A corona is an appearance of faintly-coloured rings, often seen around the sun and moon when a light, fleecy cloud passes over them, and should not be mistaken for a halo, which is much larger and more complicated in its structure, as explained above. These two phenomena are frequently confounded by inexperienced observers, but they exhibit peculiar features by which each may be easily distinguished from the other. Both exhibit the seven prismatic colours; but in a corona the colours are reversed, the red being on the outer edge instead of on the inner edge, as in a halo; and the circles of a corona, besides being smaller, are concentric with each other—the inner one being small, the diameter of the second being double, and that the third treble, the diameter of the first. The structure of the corona is quite simple, and never exhibits the attractive features observed in the halo, which is a production of comparatively rare occurrence, while a corona may be seen every time a light, transparent cloud comes between us and the sun or moon, and is produced by the diffraction of light passing between the minute globules of condensed vapour in a cloud.

What we have said regarding the size of a halo will alone enable an observer to recognise this phenomenon, and distinguish it from a corona. Professor Loomis says: "The mean of eighty-three measurements of the radius of the red circle of a halo is 21 degrees 36 minutes, which is almost identical with the radius computed from theory." The diameter of the numerous circles of a corona is not always the same, and while they are never large, the diameter of the first red ring varies from three degrees to six degrees, and that of the second red ring from five degrees to ten degrees.

A corona, like a halo, may be easily produced artificially. If we sprinkle upon a pane of glass a small quantity of lycopodium, or any very fine dust of nearly uniform fineness, and then look at the moon through this glass, we shall see it surrounded by luminous rings of prismatic colours, precisely like those that are formed by a cloud; and if, on a cold winter evening, we breathe upon a pane of glass, the breath will condense into

very small globules and freeze. If we look at the moon, or even at a street lamp, through this glass, we shall see a similar system of coloured rings, having violet on the inside.

More solar and lunar halos are usually seen in winter than in summer, owing to the favourable conditions of the former season for the formation of ice-crystals in the upper regions of the air for their production, and the singular appearances they present. During the cold weather that prevailed in the winter of 1887-8, the frosty condition of the atmosphere was particularly favourable for the production of these curious displays, and many exhibitions of the kind were observed in various portions of the country where such appearances are uncommon, and have seldom, if ever, occurred before. Many reports of such luminous circles appeared in the newspapers at that time, some of the exhibitions having been unusually interesting and remarkable; but none of the accounts seen by the writer—with one or two exceptions—explained the phenomena correctly, or mentioned their real nature, which was evidently not known, or misunderstood, by those who described them. On the evening of March 30th, 1890, a beautiful lunar halo, accompanied by a "moon-dog," was observed by the writer, and on the following morning a brilliant solar halo, with two "sun-dogs," appeared about one hour after sunrise, which attracted great attention from those who were fortunate enough to witness the interesting exhibition.

In January, 1888, a leading metropolitan newspaper published the following account, which illustrates the deceptive nature of such appearances, and the erroneous ideas regarding them: "Yesterday, shortly before noon, the sun shone through a heavy bank of dull clouds. On each side were two lesser luminaries scarcely less bright than the sun, and about the same altitude as it. Well up toward the zenith appeared two rainbows, joined like two C's placed back to back. These were not brilliant, but were clear and distinct. High above these rose two more rainbows, placed in a like manner, the colours mingling in the most harmonious blending at the junction. These two were brilliant, and the ends of each bow were as even as if cut off with a knife. At the right of the upper bow was another equally brilliant bow standing alone. This lasted several minutes, and was seen by a great number of people." Now, the "two lesser luminaries" mentioned by the writer of the above were really not "luminaries" at all, but simply parhelia, or mock-suns, the nature of which we have already explained; and the "two rainbows" were doubtless portions of an incomplete circle, or the curious arches to which we have referred, the whole representation constituting a typical solar halo, which is exceedingly rare in this portion of the country. The reference to a "rainbow" in connection with the exhibition described is certainly amusing, and it is perhaps unnecessary to state that a rainbow, though exhibiting the prismatic colours seen in a halo, is never observed in the immediate vicinity of the sun, but always in the opposite part of the heavens, and is never produced except when rain is actually falling from the clouds.

Of all the numerous weather proverbs current among the people, those relating to the production of a halo should be included with the few for which there is considerable scientific foundation, justified by actual experience and observation. There is perhaps no better known, or more popular, weather prognostic than that pertaining to the lunar halo, which has long been recognised, even among scientific persons, as an almost unfailing sign of foul weather, and reliable indication of an approaching storm. One of the old familiar proverbs relating to the lunar halo is expressed in the lines:—

"When round the moon there is a bough
The weather will be cold and rough."

Professor John Westwood Oliver, in a recent article on "The Moon and the Weather," published in *Lloyd's Magazine*, says: "The halo is an old sign of bad weather. Of sixty-one

lunar halos observed in the neighbourhood of London, thirty-four were followed by rain within twenty-four hours, nineteen by rain within four days, and only eight by no rain at all." As a halo is never seen except when the sky is hazy, it indicates that moisture is accumulating in the atmosphere, which will form clouds, and usually result in a storm. But the popular notion that the number of bright stars visible within the circle indicates the number of days before the storm will occur is without any foundation whatever, and the belief is almost too absurd to be refuted. In whatever part of the sky a lunar halo is seen, one or more bright stars are always sure to be noticed inside the luminous ring, and the number visible depends entirely upon the position of the moon. Moreover, when the sky within the circle is examined with even a small telescope hundreds of stars are visible where only one, or perhaps two or three, were perceived by the naked eye.

A lunar halo, when seen under favourable conditions, with all the curious features that usually accompany it, is one of the most interesting and beautiful exhibitions of Nature; and there are many remarkable facts connected with its formation and appearance that can not be dealt with in a popular description of the phenomenon, but which are fully explained in nearly every work on natural philosophy, meteorology, or physical geography. In Professor Loomis' "Treatise on Meteorology" may be found a clear and exhaustive description of halos and coronas, fully illustrated and scientifically explained. There is an instructive popular article entitled "The Lunar Halo," by the late Professor Proctor, in his admirable work, "Flowers of the Sky," which contains an excellent engraving illustrating the one-ring halo, most commonly observed, and showing the dark space around the moon, which is always noticed in a perfect halo, and is thoroughly explained in the above-mentioned work, together with many other paradoxical features and curious illusions associated with the wonderful atmospheric spectacle.

ARTHUR K. BARILETT.

ON DEVELOPMENT IN DAYLIGHT, ETC.

For a long time it has been sought to do without the dark-room lamp and its coloured glasses in the developing room, for the reason that it is difficult to procure commercial glasses which will only pass practically the non-actinic rays, and, on the other hand, because by means of the lantern only a very feeble light is obtained.

The methods hitherto employed have been either to previously stain the coating of the plate, or to dissolve in the developer a suitable colouring matter. It is in this manner that M. Ludwig* tints the plate, before putting it in the developer, with a solution of croceine 3B, which stains the gelatine sufficiently to prevent the action of light on the haloid salts of silver contained in the film. This is the method known as "Coxin."

A simpler method, and also an older one, consists of the addition of colouring matter to the developer without permanently colouring the film, the chosen substance completely absorbing the chemical rays, in order that they may not attack the sensitive film.

Notwithstanding its simplicity, this last method has not hitherto been generally used, owing to the difficulty of finding colouring matters fulfilling the numerous necessary conditions. These should not only make with the developer a solution coloured to absorb actinic radiations, but should not permanently colour the gelatine or provoke fog, or destroy the latent image; further, they should not stain the operator's fingers. The ability to remove the colour must be certain, especially if used for the development of papers. It is necessary also that they should be capable of use with different developers without giving precipitates, and without changing colour when mixed with the developer or with its additions (sulphite of soda, alkali, etc.)

We have methodically searched amongst the numerous commercial colouring matters for those which fulfil these conditions most perfectly, but have found none that do so absolutely. The following

colouring matters possess properties most akin to those stated: Croceine scarlet 3B, phenoflavine, ponceau 6R, uranine, tartrazine. None of these possesses the necessary properties in a sufficiently strong form to allow of development of papers with them as coloration remains which alters the freshness of prints.

We have also sought for the existence of a non-colouring substance which would destroy the sensibility of the bromide of silver without acting on the latent image, by this means permitting development in ordinary light without the addition of colouring matter. After, however, experimenting on innumerable substances, particularly the different oxydants and reducers, we have found nothing whatever with this property.

We then experimented with coloured compounds not having tintorial properties, properly so-called. After having tried a long series of materials of this nature we have found the picrates dissolved in sulphite of soda to give non-tintorial coloured solutions, and of colour capable of absorbing practically the whole of the actinic rays.

In order to be able to dissolve in water a sufficient quantity of substance we have chosen the most soluble picrates which are not precipitated by sulphite of soda. Those of soda, ammonia, and magnesium realise most fully these conditions. Picrate of ammonia could not be used, as it gives dichroic fog; pure picrate of soda gives equally as good results as that of magnesium, but the necessity of employing soda in its preparation, and the difficulty of obtaining with this alkali a perfectly neutral picrate, makes us prefer magnesium picrate.

Instead of dissolving the picrate of magnesium in the developer solutions it appeared to us more simple to mix this in a dry state in suitable proportions with anhydrous soda sulphite, and to constitute by this means a product which may be used to replace sulphite of soda in the preparation of developers. It is possible also by this means to prepare directly developers suitably coloured for development by ordinary light without having to weigh a number of substances as usually required in the preparation of an ordinary developer.

We then experimented as to the most suitable proportions of picrate of magnesium and sulphite of soda for making a mixture capable of being employed for the different commercial developers. The mixture which has given in our hands the best results is the following: 100 parts anhydrous soda sulphite, 50 parts picrate of magnesium. This mixture, used with certain developers in suitable quantities that the solution may be sufficiently rich in alkaline sulphite, gives solutions too highly coloured to enable the appearance of the image to be easily followed. We used with these developers a mixture less rich in picrate of magnesium composed as follows: 100 parts anhydrous soda sulphite, 15 parts picrate of magnesium. We have called these mixtures under the name of "chrysosulphite," that richer in picrate being No. 1, and the other No. 2.

PREPARATION OF DEVELOPERS WITH CHRYSOSULPHITE.

Developers are prepared with chrysosulphite by simply replacing in the development formulae soda sulphite by chrysosulphite. We have fixed the best proportions of chrysosulphite for use with the principal commercial developers. Chrysosulphite No. 1 is only employed with the following developers: Metoquinone, metol-hydroquinone, hydroquinone, pyrogallol acid, edinol, eikonogen, metadur, pyrocatechin, ortol. Chrysosulphite No. 2 is employed with the following developers: Diamidophenol (dianol), paramidophenol (paranol), hydramine glycine.

The following formulae are those which we have adopted with different developers:—

(I) WITH CHRYSOSULPHITE No. 1.		Edinol.	
Metoquinone (now Quinomet).			
Water	1,000 c.c.	Water	1,000
Quinomet	9 gr.	Chryso. No. 1	60
Chrysosulphite No. 1	60 gr.	Edinol	10
Acetone	50 c.c.	Tribasic sodium phosph.	60
NOTE.—In all formulae for Quinomet developer it suffices to replace soda sulphite by the same quantity of chrysosulphite No. 1.			
Eikonogen.		Ortol.	
Water	1,000 c.c.	Water	1,000
Chryso. No. 1	30 gr.	Ortol	7
Anhydrous Carb. Soda	40 gr.	Chryso. No. 1	60
Eikonogen	10 gr.	Anhydrous carb. soda	40

* 318-193 Patent, June 13th, 1902.

METOL-HYDROQUINONE.
(In 2 Solutions.)

A.		B.	
Metol.....	500 c.c.	Water.....	500 c.c.
Hydroquinone.....	2½ gr.	Anhydrous carb. soda.....	35 gr.
Chryso., No. 1.....	60 gr.		
Hydroquinone.....	4½ gr.		

For use take 100 c.c. of A and 100 c.c. of B.

HYDROQUINONE.

In 1 Solution.		In 2 Solutions.	
A.		A.	
Hydroquinone.....	1,000 c.c.	Water.....	500 c.c.
Chryso., No. 1.....	40 gr.	Hydroquinone.....	10 gr.
Hydroquinone.....	10 gr.	Chryso., No. 1.....	60 gr.
Anhydrous carb. soda.....	56 gr.		
		B.	
		Water.....	500 c.c.
		Anhydrous carb. soda.....	70 gr.

For use take 100 c.c. of A; 100 c.c. of B.

METOL.
(In 2 Solutions.)

A.		B.	
Metol.....	500 c.c.	Water.....	500 c.c.
Chryso., No. 1.....	40 gr.	Anhydrous carb. soda.....	15 gr.
Metol.....	5 gr.		

For use take 100 c.c. of A and 100 c.c. of B.

PYROGALLIC ACID.
(In 2 Solutions.)

A.		B.	
Pyrogallol.....	500 c.c.	Acetone solution.....	100 gr.
Chryso., No. 1.....	100 gr.		
Pyrogallol.....	20 gr.		

For use take 50 c.c. of A; 150 of water; 20 c.c. of acetone.

ADUROL.

(In 2 Solutions.)

A.		B.	
Adurol.....	500 c.c.	Water.....	500 c.c.
Chryso., No. 1.....	50 gr.	Anhydrous carb. soda.....	35 gr.
Adurol.....	8 gr.		

For use take 100 c.c. of A and 100 c.c. of B.

Pyrocatechin.

Pyrocatechin.....	1,000 c.c.	Pyrocatechin.....	15 gr.
Chryso. No. 1.....	40 gr.	Anhydrous Carb. Soda.....	40 gr.

WITH CHRYSOSULPHITE No. 2

Diamidophenol.		Paramidophenol.	
Diamidophenol.....	1,000 c.c.	Water.....	1,000 c.c.
Chryso. No. 2.....	30 gr.	Chryso. No. 2.....	75 gr.
Diamidophenol.....	10 gr.	Canstic lithia.....	6 gr.
		Paramidophenol.....	10 gr.

Hydramine.

Hydramine.....	1,000 c.c.	Glycine.	
Chryso. No. 2.....	16 gr.	(A)	
Hydramine.....	8 gr.	Water.....	500 c.c.
Hydramine.....	5 gr.	Glycine.....	15 gr.
		Chryso. No. 2.....	60 gr.

(B)	
Water.....	500 c.c.
Carb. of Potash.....	40 gr.
For use take 100 c.c. of (A), and 100 c.c. of (B).	

METHOD OF DEVELOPMENT.

(1.) Development of Plates and Films of Extreme Rapidity.

A.—Development in artificial light.—A sufficient quantity of developer is used to cover the plate with solution to a depth of about centimetres, about 200 c.c. for a 9 x 12 dish or a corresponding face.

The plate is taken from the dark slide in the dark-room, and put exactly into the developer. If a special lamp is not available this may be done in darkness.*

Once the plate is immersed in the developer it may be developed the light at variable distances according to the nature of the light used. The distance should be about half a metre from a candle, one from a gas jet, three-quarters of a metre from an ordinary petroleum lamp, or one and a half metres from an ordinary incandescent lamp of about 16-candle power.

Note.—In developing plates of very high sensibility it is not wise to keep the dish at such a distance during all the time of development, but it is better to place it in a less brightly lit part of the dark-room, turning the back to the source of light, and only bringing the dish to the above indicated distances when wishing to remove the plate.

The dish should be slowly rocked during development, care being

An improvised darkroom lamp. A non-actinic lamp may easily be made by using before a candle a litre bottle filled with a 50/50 solution of Chrysosulphite, placing to right and left of this bottle two other similar bottles resting on their sides. This will do instead of a lantern. Under these conditions the back of the plate should be turned to the light when lifting the plate from the slide and placing it in developer.

taken that the liquid always covers the plate. The developing formulae indicated above have been chosen in order that duration of development need not occupy longer than about five minutes. After a couple of minutes the plate may be taken out of the developing bath, turning the back to the light, examining it rapidly for a second or two by transparency, without risk of fogging. This examination should not be made, however, at a nearer distance than the following: Candle, 1 metre or 3½ ft.; petroleum lamp, 1½ metres or 5 ft.; gas flame, 2½ metres or 8 ft.; electric lamp, 3 metres or 10 ft. If it is necessary to get nearer the light, interpose a piece of yellow glass.

Fixing and washing.—When development is finished, turn the back towards the source of light, and rinse the plate in running water; then fix and wash in the usual manner.

Development in daylight.—Instead of the different sources of light mentioned, development may be carried out by daylight, provided that the sun does not shine in the workroom, and that the blind be drawn across the window by which the light is admitted. Work as far as possible from the window, and have the back turned thereto throughout development. It is not possible, however, without risk of fogging, to examine the plate by transparency, unless an upright glass tank be used. The plates are placed in the bath, washed and fixed exactly in the preceding manner.

(2.) Development of Lantern Plates.

By reason of their lower sensibility lantern plates may be developed without taking further precautions for the lighting of the room than for bromide papers (see under). For black-toned lantern plates the same formulae for development may be employed as those given for papers.

(3.) Development of Bromide Papers.

A.—By daylight.—Two formulae follow for development of bromide papers that have given good results:—

Quinomet.		Diamidophenol.	
Water.....	100 c.c.	Water.....	100 c.c.
Quinomet.....	0.9 gr.	Chrysosulphite No. 2.....	3 gr.
Chrysosulphite No. 1.....	6 gr.	Diamidophenol.....	1 gr.
Acetone.....	33 c.c.	10% solution pot. bromide.....	2 or 3 drops
10% solution pot. bromide.....		2 or 3 drops	

Development may be carried out without other precautions than keeping the corners of the paper at the bottom of the dish to prevent the paper floating, lighting by the different sources of light given above, without taking account of the distances indicated for plates. One may approach sufficiently near to the light to follow easily all the phases of development.

Exposure, however, should be sufficient to prevent development occupying longer than about 40 to 50 seconds. The papers are placed in the developing bath exactly in the same manner as plates.

B.—By artificial light.—Operations by this method are carried out in the same manner as for plates. Care should be taken that the corners of the paper are kept at the bottom of dish, as if they are not submerged they will veil quickly. They may be fixed in daylight, employing a fixing bath coloured yellow or orange by a little chrysosulphite. Fixing done, they should be abundantly washed in the ordinary manner until the back is perfectly clear.

Finally, the mixtures of sulphite of soda with picrates, and particularly with picrate of magnesium, give coloured aqueous solutions which directly absorb the actinic rays and permit development to be easily controlled. These solutions do not colour the gelatine or paper in a persistent manner, will not stain the fingers, and will show every advantage that may be sought in rendering possible development in ordinary light.

A. and L. LUMIERE and A. SEYEWETZ.

SOUTH Essex Camera Club.—Under this title in future the East Ham Teachers' Photographic Society will be conducted (Mr. Walter D. Welford, F.R.P.S., President). The club is open to lady and gentlemen photographers in East Ham, Stratford, Leytonstone, Ilford, Barkings, and the surrounding district generally. The next meeting is on March 9th, when Mr. H. W. Bennet, F.R.P.S., will lecture upon "Control in Printing." Visitors are invited, and all information may be obtained from Mr. R. P. W. Rotherham, 270, Thorold Road, Ilford.

SOME RAMBLING OBSERVATIONS ON THE METRIC SYSTEM.

It is an amusing and not uninteresting play to put oneself quite outside of the decimal periodic system of expressing numbers and notice the difference between the properties of an abstract number and its numeral.

We can do this by supposing we have eight or twelve digits instead of ten. With the former number seven will be the largest number to be expressed with a single digit, eight will be expressed with two; or in the latter case we can keep the present digits up to nine and invent two new ones for ten and eleven, so that the smallest number requiring two digits will be twelve, which will be written ten. The square of ten, or 100, will then be a gross, and 1,000 will stand for twelve gross.

This duodecimal system is really better than our present, although we shall never be able to change to it. We use ten digits not because this is a better number than eight or twelve, but because our ancestors in India, whence the ten digit system was brought to us by the Arabs, had ten fingers, and not eight or twelve. Having ten digits it is easy to calculate in tens and its powers. If we had twelve digits it would be equally easy to calculate in dozens and gross, then the multiplication table would seem odd to us. 5×6 would be 26 0.9 would be three-quarters, 6 would be half of ten. Then the magic properties of nine would disappear, it being no longer the largest of the single digits, and eleven would become the pet of fortune-tellers. The number 100, being nothing but the square of 5×2 , would hardly be more important than is the square of 7×2 now. It would be written 84, and nobody would use it to express the rates of interest, or the number of years in a natural division of time, or as a convenient number to express the strength of a solution. A small boy who was asked to calculate in "per gross," the strength of a solution of one part in ten, would say to himself that no one but a fool of an examiner would ever think of making up such a solution. The answer would be 12.4972 . . . parts per 100, which the reader will do well to calculate for himself, using the letter T for ten, and see how he is tied to the "wheel of things."

It is difficult to think in abstract numbers. Forty millions would seem to be most certainly a naturally important even number. But suppose a meter stick to be dropped on to a neighbouring planet, with the information somehow conveyed that it is an aliquot part of the planet earth's circumference. The stick is given to a professor of mathematics, who hands it over to his assistant. The assistant reports that it is of such a length that 11,490,194 are equal to the circumference of the earth. "That is quite impossible," the professor would say, "either there is some error or—," and here an idea would strike him. "Just factor that number will you?" The factors would prove to be $5^7 \times 2^3$, and this would show that for some strange reason the inhabitants of the earth used a periodic system of ten digits instead of twelve. Possibly the professor might be shrewd enough to conclude that they had originally only ten tail-feathers.

The most important numbers are two and three, and the multiples of these raised to various powers. If we used a system of eight or twelve digits to express these multiples, we could multiply and divide them as easily as we can the decimal numbers, which are multiples of five and two. Since we cannot we sometimes prefer to take the case of multiplying, more often than we should we prefer the natural multiples.

Thus for instance a dozen is a natural common multiple. It is a natural number of dry plates to put into a box, and when these plates cost a shilling a dozen then each plate costs a penny, and only one change is necessary for a perfect system, namely, to write that dozen ten, and a gross 100. But we cannot make this change. A sheet of paper can be folded into thirds, quarters, eighths, twelfths, and sixteenths; not so well into fifths and tenths. The shilling, foot, and clock-dial are divided into twelve parts, the pound, inch, and bushels into eighths and its sub-divisions. If we had the best possible system of expressing numbers, these natural divisions would also be the easiest to use. We have not this system, and all we can do is to compromise; to use decimals whenever we can, and dozens and sixteens as little as possible, and that is what the metric system does. It is useless to attempt to improve this system, for its weak points belong to the use of ten digits, a number not divisible by four or three.

Here in Germany the metric system is in universal use, and it is interesting to watch this conflict between the artificial ease of dealing

in tenths that results from the use of ten digits, and the natural tendency to use the simpler factors and multiples.

The weights in an ordinary shop are the kilogram and half kilogram (1,000 and 500 grams), and the smaller 200, 100, 50, 20, 10, 5, 2, and 1 gram weights. These smaller weights are made of brass and are stamped in grams, the larger from half kilo up are stamped in kilos. They all have a knob, which is not really necessary for small weights, and makes it difficult to read the numbers. It would be better to have these smaller weights cast with a flat top and large raised numerals.

If you go into a shop in Germany and ask the price of something you are told it is so much a pound, by which is meant the half kilogram. Most countries had a pound weight before the metric system was introduced, and these pounds were not very different in mass from one another and the half kilo, so the latter was called a pound. No doubt it will be called a pound in England and America. It is a pity that we cannot then grumble about the good old honest pound for the new one will be larger by ten per cent. But at any rate the Germans will then have to stop picturing a pair of scales with the English pound of meat extract badly outclassed by the German pound. And our friend with the bass drum can no longer get excited about the smallness of the American gallon of paste. On the other hand the litre will of course be called a quart, and it will not be as large as the old quart, that is, not in England. In America it will be larger.

Goods put up in English pounds may not be sold in Germany, the writer has been informed, if so marked. For instance, quarter pound parcels of tea must be marked "115 grams of tea" in order that the buyer may clearly understand that he is not getting 125 grams, that is the quarter of the half kilo. Something of the sort will be necessary in America and England. It will probably be necessary to prohibit the use of the word "pound" even when qualified by "old" or "avoirdupois," if it is also used for the half kilo.

To return to the shop in Germany, you may perhaps order by weight a pound of the substance you want. For this very common order the dealer has no single weight, because half a pound is a quarter of kilo, and the decimal system deals only in halves and fifths. He puts on a 200 and a 50 gram weight. If you order a quarter of a pound, also a very common order, he puts on the 100 gram, the 50, and the 5. Sometimes if in a hurry he uses the two first only, and gives good weight for the missing 5. Sometimes the three weights are tied together with a string. If you order three-quarters of a pound it is necessary to use the 200, 100, 50, 20 and 5 gram weights and it is not easy to identify all of these, because the numerals are not conspicuous.

Here we see the disadvantage of the decimal system. If a pound is too much the average person does not and perhaps never will consider all the tenths, but rather three-quarters, a half, a quarter, an eighth. With a set of avoirdupois weights the dealer uses a half and quarter to get the three-quarters. If we had an eight digit system he could do this exactly as at present. Even with a decimal system, which is not so favourable for dividing in eighths, only three weights would be required for the three-eighths of a kilogram that require five in the metric system.

Below a quarter of a pound (125 grams) here in Germany they usually switch off on to decimals, ordering 100 grams or 50 grams etc. This change is not difficult (and this is an important point for Englishmen to note), because the coinage is decimal. If a substance costs M3.50 a pound, 50 grams will cost 35 pfennigs and 100 grams 70 pfennigs. But in England this will not do. Having learned to calculate what a quarter, eighth, and sixteenth of a pound will come at so many shillings and pence a pound, the Englishman is not going to learn to take a fifth, tenth and twentieth of this sum as well. He will demand four ounces and get 125 grams, two ounces and get 50 grams, one ounce and will get 31 grams; that is, the quarter, eighth and sixteenth of the new pound. Possibly the Government recognizes this tendency to order as of gold, might allow weights to be made of these masses, of a different shape, so as to be easily distinguishable from the decimal weights. The least of these being 31.25 grams, a sixteenth of the new pound, would be ten per cent. larger than avoirdupois ounce, and therefore nearly equal to the troy ounce. By dividing the litre into thirty-two parts (as the quart is in America) the confusion between troy, avoirdupois and liquid ounce is removed. The new ounce would probably be divided into drachms.

grains so that the gram weight and the decimal parts of the kilo would disappear altogether from practical use. These changes would simplify matters somewhat. The larger units of weight and volume would be identical with those of other countries. Three ounces would be satisfactorily amalgamated, the minim of water would weigh a grain, and the confusion between the various terms would disappear. On the other hand another ounce, drachm, minim, grain, quart, and pound would be added to the present supply, and the advantage of the decimal system would be lost, except in small measures. The change would hardly be worth making; a jump in the frying pan into the boiling tea-kettle; from an ounce of 28 grains to one of 31.25 grams. An alternative would be to make a new ounce 32 grams, which would simplify the relationship between smaller weights, but at the expense of unity amongst the larger. The other change is really worth making. We must go over wholly to the decimal system. We must learn to think in tenths below a half quarter. We might add two weights to those used in Germany, a half and a quarter "pound," and below these switch off on to decimals; "switching" will not be difficult in the United States, because the American coinage is decimal, but in England the whole change to the metric system can only be made successfully by changing the coinage to the decimal system, that is by dividing the shilling into one hundred parts. What is required is firstly that the unit of length shall determine the unit of volume, and the mass of the unit volume of water shall be the unit of weight; and secondly, that these units and the coinage shall be divided and multiplied in agreement with the periodic system of numbering. That this fundamental unit of length be the yard is not so important as that these other conditions be fulfilled, including that of dividing the shilling into one hundred parts. But Russia is going to change along with the United States and England would be very much better not only for Russia, but also for the other two countries to have Russia adopt the same fundamental unit. It would be a great advantage in exporting goods to Russia, and the other parts of the world Russia may soon be finding herself unable to do. This would certainly not be the case if the English inch were retained. After all, no better unit and system than the metrical can be devised as long as we use a number of digits not divisible by three or four.

DUODECIMAL.

A MAN WHO HAS A DIFFICULTY ABOUT GETTING IN HIS ACCOUNTS.

(From "Process Work.")

SIR,—Yours is the old trouble. Everyone who is in business knows it. The man who won't pay up is the bugbear of all business, big or little, successful or otherwise. Business life would be comparatively easy and certainly free from half the worries and anxieties which now attend it if we could only deal with people who have ready money, or who can be trusted to settle regularly and promptly if they take credit. But this is an impossible ideal. In any business there will be some customers who are irregular with their payments, being unsafe to trust, and for such it is justifiable to make special provisions. Like all exceptions, however, they prove the rule, and expediency and discretion must teach us when to depart from it. To know when and to whom to give credit is an art in itself which cannot be taught; it is generally learnt by bitter experience. The way to avoid having bad eggs in your business basket is not to let them get there. When you get a new customer who wants to try your first duty is to eye him with suspicion. You ought to have some good reason why he wants your goods without paying cash for them, and you want a still better reason for knowing whether he is in a position to pay for them when you have extended him the credit he has asked for. He may have great hopes and expectations, but these things don't pay the people from whom you buy your stuff, and even if you make it yourself you have work to do whose expectations only last six days and who expect to be paid at the end thereof. If you are so foolish as to accept orders from every Tom, Dick, or Harry who comes along without understanding as to terms of payment you must expect to have trouble about getting your accounts in. A man can't go to a shop and demand cash over the counter without giving some equivalent for it, and there is no reason why you should let any one have your goods, which are the same thing as cash, unless he can show his ability to pay for them. It may be a delicate question

to put to a customer, but you need not put it bluntly, perhaps you need not put it at all, if you know the class of man you are dealing with. There is generally some indication to warn you as to the character of your customer. It is fortunate that the kind of man who is not likely to pay generally shows the cloven hoof. He betrays some traits or characteristics that warn the keen sighted man of business how to deal with him. He is probably plausible, affable, and flattering, lavish in giving orders, careless as to the price of your goods, and not exacting as to discounts. When you encounter a man of that kind you will almost always find out afterwards that he is lacking in judgment, wanting in energy, inattentive to business, lacking in punctuality, reckless in promises, and wanting in principle. Just as there is seldom a storm without some previous indications of its coming, so there will always be some premonitions of the character of the unsatisfactory class of customer, and if you neglect these warnings you have only yourself to blame if you suffer the consequences. Even though you may take all possible precautions to weed out undesirable customers, you may still get them, as all firms do. Various methods have been adopted for dealing with them, but most methods end up with the matter-of-fact argument of the solicitor's letter. With a certain class, not necessarily the dishonest ones, no other form of persuasion is of any avail. You may decorate the accounts with rubber stamps, and stick little flags on them—red, blue, yellow, black, or any colour you like—following this up with letters of more or less mild remonstrance, but the case-hardened debtor is proof against it all. He knows the routine, and waits for the lawyer's letter, sometimes even for the County Court summons before he scrapes up the needful. This class of customer is, however, generally cheerful about it, considering perhaps it has paid him to gain time. Another class, which we all know, wax indignant about the receipt of the solicitor's letter, and probably write something like this:—"I am surprised that you have done such a dirty action as to press me for my account. I shall never trouble you with any more orders," etc., etc. When a man writes like that I think you can generally make up your mind to do without his orders. I never knew a man who wrote like that whose orders were worth anything. The good business man who is honestly in difficulty does not meet a request for payment in that way, in fact, he never lets it get to that stage. He manfully makes a clean breast of it and asks for time, which no good business house will refuse him, because we can all sympathise with the man who is honestly in a tight corner. We have all been there at times and know what it is.

This is about all the advice I can give you on this vexed question of getting your money in. I would only say in conclusion that you must steel your heart to be firm with your debtors. You must learn to say "No" in this matter when you feel that the occasion demands the direct negative. If you want something to stiffen your backbone, get it into your mind that to lose money by a bad debt is not your loss only, but the loss of those who are dependent on you. You must feel as the great lawyer Erskine said he did when he was making his way in the world, that your children are tugging at your coat-tails.—Yours sincerely,

JONATHAN JOBLOT.

MESSRS. W. WATSON AND SONS, of 313, High Holborn, London, W.C., notify that they can now supply the Patent Antinous Shutter Release in a form suitable for use on the Goerz Sector Shutter. The price remains the same as for the other patterns, viz., 2s. 6d.

PHOTOGRAPHIC Survey and Record of Surrey.—The annual meeting will be held, by kind permission of the Mayor of Croydon, in the Council Chamber, Town Hall, Croydon, at 8 p.m., on Saturday, March 12th, 1904. The President, Viscount Midleton, will give an address, and the report of the Council and the accounts of the year ended 31st December, 1903, will be submitted. The meeting is open, not only to members of and contributors to the Survey, but to all interested in its work and aims. Arrangements have been made for an exhibition, consisting of a representative selection from the 700 prints already in the Survey collection, in the Lecture Room, Town Hall, Croydon. This will be open on the day of meeting, from 3 to 9 p.m., and again on the following Monday, Tuesday, and Wednesday, from 3 to 5 p.m., and 7 to 9 p.m. A short lecture, illustrated by lantern slides, will be given each day.

THE INVARIABILITY OF THE WAVE-LENGTHS IN THE SPARK AND ARC SPECTRUM OF ZINC.

[From the "Chemical News."]

I.

THE breadth of the lines in the arc and spark spectrum is a complicated, and as yet only partially known function of the temperature, pressure, and the density of the luminous layer of vapour (H. Kayser*), and is probably dependent on the kind of electric excitation, and of the dielectric (Hartmann†). The experimental observations of these phenomena of broadening are as yet by no means finally concluded. In particular it is not yet known whether the intensity maximum—in a certain measure the centre of gravity of a spectral line—is displaced when it broadens or not, which is a question of fundamental importance for the whole of spectrum analysis.

Actual displacements of spectral lines (i.e., clearly demonstrable alterations of the wave-lengths) have undoubtedly been proved by Humphrey and Mohler‡ as a consequence of variable external pressure.

But F. Exner and E. Haschek went distinctly further when they said that these displacements occurred with greater intensity in the spark spectrum than in the arc, and depended not only upon the external atmospheric pressure, but also on the partial density of the vapour under examination (Exner and Haschek, "Wellenlängen Tabellen für Spektralanalytische Untersuchungen," Leipzig und Wien, 1902, p. 13). They further stated that many spark spectra show considerable displacements of the spark lines as opposed to the analogous lines in the arc spectrum (in both cases at ordinary external atmospheric pressure), and tried to explain this by the pressure phenomena in the spark (These *Sitzungsber.*, 1897, et seq.), and would calculate from the magnitude of the displacements of the lines the magnitude of the pressure in the spark; E. Haschek and H. Mache (These *Sitzungsber.*, 1898) tried to demonstrate the pressure in the spark directly, but could obtain no agreement of the values calculated from the "displacement of the line" with the observed values. From his further researches, E. Haschek (These *Sitzungsber.*, Bd. ex., Abt., II.a, März, 1901, p. 181) afterwards concluded that the laws which hold good for the displacements of the lines in the spark are different from those which obtain in the case of the arc, and that therefore a calculation of the spark pressure from the displacement of the lines is not admissible; the spark pressure observed from Haschek's measurement showed so little agreement with that calculated by him that he himself said: "The calculated pressures differ so much among themselves that there can be no doubt that other causes are responsible for the displacements of the lines" (Haschek, *loc. cit.*). As such another cause of the "line displacements" Haschek mentions "the increasing density of the luminous vapour"; with equal increase of the vapour density it is said that "the lines in the spark spectrum are displaced more than those in the arc spectrum"; thus, for example, according to Haschek, in the zinc spectrum the lines λ 3282, 3302, 4680, 4722 have in the spark spectrum a wave-length greater by 0.03 to 0.16 Angström units than in the arc; in other cases Haschek mentions displacements up to 0.2 A.U. for elements with many lines, and up to 0.07 A.U. for elements with few lines, which are very considerable amounts, lying far beyond the limits of errors of observation permissible with grating spectra. As a proof of the correctness of these observations he performed numerous wave-length measurements (with different elements, e.g., B, Al, Zn, Ca, Si, Zr, Cr, Ti, Ce, Va, etc.). From these statements it seemed as if the existence of real line displacements was certainly proved for the spark (as opposed to the arc lines) for ordinary external atmospheric pressure. Also the quantity of the vaporising substance, according to Haschek, is said to have an appreciable influence on the actual wave-length of the lines, so that

* "Handbuch der Spektroskopie," Leipzig, 1902, Bd. II., p. 296.

† *Sitzungsber. der Königl. Preussischen Akad. der Wiss.*, Berlin, 1903, pp. 40 and 234.

‡ *Astrophys. Journ.*, 1896 and 1897. Humphrey and Mohler increased the pressure of the gas, in which the arc is produced, to several atmospheres, and observed the displacement of some spectral lines towards the red, and they found that the increase of wave-length is proportional to the pressure of the surrounding gas.

§ No notice at all is taken in this treatise of displacements of lines caused by rapid movement of the sources of light in the radius of vision in the sense of Doppler's principle, which displacements are used for the measurement of the movement of the stars in the radius of vision.

|| Meanwhile, N. A. Kent has proved that in the case of the titanium lines Haschek's displacements of 0.13 A.U. do not exist (*Astrophys. Journ.*, 1903, Bd. xvii., p. 286).

in his opinion a method of quantitative spectrum analysis could be based on the measurement of these so-called line displacements (These *Sitzungsber.*, Bd. xli., Abt. II.a, February, 1902, p. 232). For example, for pure zinc (spark spectrum) the wave-length 4722.510 is said to be correct, while it amounts only to 4722.399 for the same zinc line, using a 5 per cent. zinc alloy instead of pure zinc as electrode. Thus the partial density in the luminous vapour would have a definite influence on the wave-length.

The theory relating to the dependence of the wave-length of the spectral lines on the partial density of the vapour under examination occupies a prominent position in the work by F. Exner and E. Haschek, "Wellenlängentabellen für Spektralanalytische Untersuchungen auf Grund der Ultra-violetten Funkenspektren der Elemente" (Leipzig und Wien, 1902, I. Teil., p. 13). The comprehensive numerical results which the above authors give as obtained in their wave-length measurements would force us to acknowledge the value of this evidence in their favour, if we could suppress our well grounded doubt concerning the value of the evidence afforded by their photographic material.

On an earlier occasion we had already obtained results which did not agree with their statements in the case of the spark spectra of calcium and lithium, as we pointed out at the time (we drew attention to the fact that photographic errors might have occurred*), and when we began new wave-length measurements in the zinc spectrum we again met with experimental results which were contradictory to Haschek's statements. Also our results with regard to the spectra of alloys both poorer and richer in zinc do not agree with Haschek's statements and measurements.

H. Kayser, of Bonn ("Handbuch der Spektroskopie," Bd. II., pp. 297, 308, 309, and 310), also opposed Exner and Haschek's statements; he stated that during his spectroscopic researches on the electric arc he had never observed any influence exerted by the mass of the element present on the wave-length, and according to his view the partial pressure of the vapour in the arc could produce no displacements, as can be easily proved if we work with apparatus of considerable resolving force, while otherwise apparent displacements may result. As regards the comparison of the wave-length in the spark with the arc lines, and the influence of the partial pressure on displacements of the lines in the spark spectrum, we present no further experimental confirmation exists regarding Exner and Haschek's assumption of displacements of the lines.

It may here be stated explicitly that it is not a question of the breadth of the lines in the so-called asymmetrical phenomenon of broadening, which has been known for many years, and which amongst other things manifests itself in such a way that with pure metal electrodes (e.g., zinc, lead, etc.) spectral lines in the spark from a jar are decidedly broadened towards the red, and, on the other hand, the same lines become fairly well defined if these metals in the electrode occur only as small impurities (thus with small partial density) in the vapour. In the case of Exner and Haschek's phenomenon of the displacement of the lines, it is a question rather of the exact wave-length of the intensity maximum of the lines† which, in a certain measure, represents the "centre of gravity" of the lines concerned.

If we take as basis for such measurements the intensity maximum of the lines in question, which is now recognised both generally and also by Haschek (These "Sitzungsber.," 1902, Bd. III., Abt. II.a, p. 233) as the only permissible method of taking such measurements with correct photographic procedure, and the most accurate possible resolution of the spectra, we arrive at results which contradict Haschek's statements.

We first attacked the zinc spectrum and devoted ourselves exclusively for a long time to eight zinc lines, which could be taken as typical, and which, in addition to other similar spectra, were brought forward by Haschek as affording specially valuable evidence in favour of his theory.

Our grating is an excellent large Rowland's concave grating with radius of curvature of 15 English feet (i.e., the same radius of curvature as that of the grating used by Exner and Haschek), which H. Kayser of Bonn, who saw our spectrum photographs, calls a grating "of the very first order." Now, with asymmetrically broadened lines—

* Eder and Valenta, "Über das Funkenspektrum des Calciums und Lithiums Seine Verbreiterungs und Umkehrerscheinungen," *Denkschr. Akad. der Wiss. Wien*, 1898, Bd. lxvii.

† Specially discussed and illustrated by us in our treatise, "Funkenspektrum des Calciums und Lithiums und Seine Verbreiterungs und Umkehrerscheinungen" (*Wiener Akad. Denkschr.* 1898).

Herschel's research only applies to such—the possibility of finding the intensity maximum with certainty depends on restricting the broadened band part by the most careful photographic procedure. We worked with a slit of 0.008 to 0.03 m.m. breadth (sharp steel knife edges), which last even gave good definition of the lines, ascertained the photographic focus of the grating by empirically removing the photographic plates $\frac{1}{2}$ m.m. at a time, and bent the photographic error plates confocally with the curvature of the image. We arranged the photographing of the lines one over the other in such a way that a blind for the slit, which could be easily removed to and from, could be interposed before the photographic apparatus, and by giving this blind every line could be photographed in three parts one after the other. At each separate operation the whole grating was fully illuminated. The illumination of the plate was short.

No agreement has yet been arrived at regarding the idea of a "short illumination" or "minimum illumination" with the best clearness and sharpness and correct development. As long as this is the case, differences of observations with regard to the so-called displacement phenomena of spectral lines, as E. Haschek repeatedly describes them, in contradiction to other spectroscopists, will exist, and it will be difficult to avoid deception. In order to fix definitely the sharpness of the lines, the breadth of the measured lines should not only be expressed in Angström units (A.U.), but the "degree of blackening" of the line in question on the photographic negative should also be given; the latter could be fairly small. It may be regarded as a criterion whether a photograph will meet the strictest requirements if an asymmetrically broadened line is obtained with medium or least blackening with a certain minimum breadth. We measured the breadth of the sharp iron lines resulting under favourable experimental conditions in the arc spectrum; they were, for example, 0.03 to 0.04 m.m. broad with a slit 0.03 m.m. breadth (with minimum illumination) when they produced, measured in Hartmann's microphotometer a blackening of 0.5 to 1.0; while the zinc lines, when strongly subjected to the broadening under exactly the same conditions, were never narrower than 0.06 m.m. in the negative of the spectrum. If the scale is reduced to A.U. the zinc line 810 has thus in the arc a breadth of 0.07 A.U. against 0.19 A.U. in the spark (in both cases with minimum illumination); nevertheless, we can easily prove the coincidence of the two lines at the position of their greatest light intensity. But if we illuminate the zinc spark twice as long, the asymmetrical broadening is so marked that the total breadth of the line amounts to 0.53 to 0.71 A.U., and then it is difficult to find the maximum of the light intensity; the central part of the line is shifted towards the red; but it is still possible to think that the maximum has been reached, and thus an apparent displacement of 0.003 A.U. may be found, which increases to 0.02 A.U., and with long illumination, bad development, and imperfect reading in consequence of feeble light, can amount to still more. The reason for this apparent displacement is to be found in the fact that the central part of the line is not more resolved. Also the placing has an appreciable influence. When it is not perfectly exact, asymmetrically broadened lines become recognisable and disappear.

It is difficult to decide whether this is sufficient to explain the very contradictory statements of different spectroscopists who have photographed one and the same phenomenon, but it is a fact that by carefully carrying out the spectrographic process as described, we succeeded in proving the non-existence of all alleged displacement phenomena, which Haschek described for zinc, as well as for other spectra.

J. M. EDER and E. VALENTA.

The "Daily Chronicle," in conjunction with Messrs. G. W. Bacon and Co., Ltd., and with the help of a geographical expert, have compiled a War Map, comprising the principal districts of the war; special inset of Port Arthur is also included. The book, however, comprises a complete Guide to the War, the work of an expert. The "Daily Chronicle" War Guide includes a sketch of the Korean-Manchurian Question, a tabulated comparison of the armed strength of the nations, the history of the war up-to-date, and an A.B.C. guide of places, people, and points of interest. The "Daily Chronicle" War Map can be obtained from Messrs. Edward Lloyd, Ltd., 12, Salisbury Square, for 1s. 1d. post free.

In such spectrum photographs, in which the highest definition is required, a range of 1 mm. in the plane of position (with a total focus of 6 m.) produces very considerable disturbances.

COPYRIGHT NOTES.

THE committee of the Photographic Copyright Union has decided to issue an occasional paper in order to keep better in touch with their members and to inform them as to their doings, which must in itself prove most useful, especially as the great advantage of committee and members being united and stimulating each other cannot be over-estimated.

SPECIAL NOTES.

At our annual meeting a member thought it would be desirable that it should be clearly understood that whenever any doubt is felt as to the amount of fees to be charged, etc., the secretary of the Union should be consulted on the subject. At the same time it will not be out of place on the present occasion to print the following suggestions which have been so clearly and carefully drawn up by a member of the committee, Mr. Alfred Ellis.

Permission to Reproduce.—Members are advised not to give permission for their copyright photographs to be reproduced until they have full particulars of the size and style of the proposed reproduction, when they can formulate their charges accordingly. For example: a newspaper should pay a fee of not less than 10s. 6d. for half-tone black-and-white reproduction not exceeding 6 by 4 inches, when printed with letterpress in one issue of a newspaper; but, if it is to be printed as an inset the fee should be at least one guinea. If printed in colours, collotype, or photogravure, it should be a still higher fee. If a photograph is to be reproduced for advertising purposes, a higher fee should be charged than for newspaper work. In all cases, the permission must be in writing, and should state the fee to be paid, the process by which the photograph is to be reproduced, and whether in black-and-white or colours, the size limit, and the purpose for which the reproduction may be used.

The fee for reproduction on post-cards should be not less than 10s. 6d. royalty per thousand for half-tone or collotype, and £1 1s. per thousand for bromide or ordinary photographic processes.

On the same occasion sincere regret was expressed that so many photographers, whilst sympathising with the objects of the Union, felt debarred for certain reasons from joining as members. At the same time they acknowledged having benefited by the existence and influence of the Union, and consequently would be willing to support it financially if they knew that such help would be welcomed. We need hardly say that such assistance would be most welcome and friends thus helping would be styled contributors and doubtless as they became more in touch with the important work and realised the duty to help by personal adhesion to Rule 23, they would soon become full members.

Reasons for not Joining!—Will our members, when they hear of difficulties in the way of friends joining, communicate at once with the secretary, so that the matter may be brought before the committee for their consideration and see if they can be met consistently with adhesion to Rule 23.

The Work Done.—No one outside the committee has the slightest idea of the importance of the business usually transacted at its periodical meetings, and the reading of the secretary's "Log Book" of work done during the previous month, would convince not only members, but also those still holding aloof from its membership, of the great service which the P.C.U. renders to photographers generally. Surely the annual report printed in the present number speaks eloquently for itself.

Just Ask!—So often when permission to reproduce is sought by editors and publishers, the preparedness of certain members to charge fees lower than the minimum is quoted as a lever to secure more liberal terms and consequently the photographer applied to finds it very difficult to know what to do. Our advice is—write and ask the photographer whose name is mentioned if such information is correct, or failing that communicate with the secretary.

We would strongly recommend photographers to be very wary in dealing or selling rights to reproduce their copyrights for post-cards or in any cheap form, moreover not to accept any ordinary fee, but to insist upon a royalty, the amount of such royalty to be mutually agreed upon, on the basis of the number printed, etc. There is no doubt that the sale of photographs has been absolutely spoilt by the indiscriminate sale of copyrights for these cheap reproductions at ridiculously inadequate fees. The secretary of the Union will always be happy to give advice on the subject, the matter having often been discussed in committee.

The secretary has copies of the late Mr. Elliott's useful pamphlet entitled "A Few Facts Relating to Photographic Copyright," which has rendered such good service in placing the question of photographic copyright clearly and authoritatively before our brethren generally. If you have lost your copy, send for another one; or if you never had one, by all means write at once.

Will our members remember that the secretary is always at their command to answer questions, to register photographs at Stationers' Hall, and give advice on all questions of copyright, to help in fixing the amount of fees to be charged, and to suggest the form in which permission should be drawn up and assignments made, and in short to help our members generally.

Subscriptions are now due and should be sent at once to the secretary, at 23, Soho Square, London, W.

PHOTOGRAPHY AS A PROFESSION.

[Extract from "Works of the Nation," by Elison Willets.]

WITH the rise of the illustrated daily paper, with the impetus given to weekly journalism by the camera, with the advent of ten-cent illustrated magazines, professional photographers were divided into two great groups; the studio photographer and the newspaper photographer. The studio photographer includes the conservative element representing all the traditions of the art; the newspaper photographer scorns tradition and proceeds to take pictures at any time and at any place, by night as well as by day, making the whole world his studio.

The studio photographer takes pictures by rule. He studies light and shadows and the pose of the sitter, and consequently his pictures may represent expression, but seldom action. The newspaper photographer has no time for rules, does not study light and shadow, has no regard for the position of the head, hands, or feet of the persons whose appearance he is about to perpetuate—in short, he is the realist of photography; his pictures show persons as they are in everyday life, in their usual pursuits or on extraordinary occasions. Many of the pictures made by news-photographers are of vastly greater importance than those made in the studios. The work of the news-photographer is of greater educational influence than all the nice, "look-pleasant," dead-calm pictures made under skylights.

The great demand for photographs by newspaper and periodical editors and publishers has caused a large number of amateurs to enter the field as professionals. Having reached a creditable degree of excellence in photographic work as a fad or as a source of amusement and pleasure, the amateurs have proceeded to master every detail of the work, and are now pursuing it as a business. Those who are ambitious, those who, as amateurs, were energetic and painstaking, are making a success as professionals. As a professional, of course, a small capital is required, but capital is not the only requisite—the professional must possess energy and enterprise and courage. He must know how to secure patrons if he is a studio photographer, and he must study the market for pictures if he is a newspaper photographer. In addition to the demand created by the illustrated papers, the scientific world makes many demands upon the camera. Physics, mechanics, astronomy, chemistry, zoology—all these branches of science give employment to enterprising photographers. Science now demands pictures of birds in flight and of animals in motion. Such pictures bring a high price.

NEWS-PHOTOGRAPHERS.

The successful newspaper photographer is one who can take pictures without the accessories of the photographic gallery. He is one who can use the camera by night as well as by day, at sea as well as on land; briefly, he is one who can take a picture of anything under any circumstances, and who can sell the picture after he has made it. He must make good pictures under conditions the most unfavourable. He must be able to photograph the deck of a movable battleship from the Brooklyn Bridge; he must be able to take pictures of the manoeuvres of a troop of cavalry when his camera faces the sun; he must photograph the celebrity as he comes down the gang-plank; the President of the United States while he is making a speech from the platform of a railroad train; the bride as she comes forth from the church.

The nature of their duties has made the leading newspaper photo-

graphers rich in experience at least. During the last four years Mr. James H. Hare, as the staff photographer of "Collier's Weekly," has been present at almost every event of national importance which has taken place in this hemisphere between San Francisco and Halifax and between Manitoba and Venezuela. When Mr. McKinley made his transcontinental tour, Hare was on the train. When the beloved President was shot at Buffalo Hare was present, and it was indeed he who, in picturing Mr. McKinley as he mounted the steps of the Temple of Music, took the last photograph of the living President. Four days after the "Maine" disaster in Havana harbour, Hare was on the scene with his omniscient camera, and that same instrument recorded all the exciting events that took place in the Cuban capital before the war. When war was declared, Hare shouldered his camera instead of rifle, and marched with the troops to the very firing line. In camp and under fire, in the depths of the Cuban forests in search of Gomez, and on the transport on the way back to Montauk Point, Hare continually "pressed the button." Since the war, the launching of every battleship, the scene following every flood and great fire, every wreck cast up on our shores, every international or intercollegiate athletic contest, every political convocation, all the manoeuvres of the army and navy, and, indeed, every event having a place in news has been pictured either by himself or by his colleagues on "Collier's Weekly." Hare's work serves as an example of what is expected of the modern newspaper photographer. The narrative of his experience, between the covers of a book, would show that the newspaper photographer's life, as well as that of the correspondent, is intimately connected with all that is picturesque and dramatic.

Patent News.

The following applications for patents were made between February 15th and February 20th, 1904:—

Negative Boxes.—No. 3,773. "Improvements in boxes for transporting photographic negatives and the like." Joseph Hart Balfour.

Flash-lights.—No. 3,794. "Improvements in the flash-lights for photography." (Actien-Gesellschaft für Anilin Fabrikation, Germany.) Charles Denton Abel.

Developing Machines.—No. 3,799. "Improvements in or relating to photographic developing machines." (Frank A. Brownell, United States.) Kodak, Limited.

Dark Slide Adapter.—No. 3,822. "A new dark slide adapter." Howard Seymour Taylor.

Washing Apparatus.—No. 3,830. "Improvements in apparatus for washing and draining photographic plates." John Henry Sykes.

Tissues.—No. 3,855. "A process for preparing photographic tissues." Complete specification. Ignaz Hoffsummer.

Printing Apparatus.—No. 3,900. "Improvements in apparatus for the production of prints by photography or combined with typographic or other printing." Oscar Robert Richter.

Film Plates and Holders.—No. 4,018. "Improvements in photographic film plates and plate holders therefor." James Wyndham Meek.

Cameras.—No. 4,127. "Improvements in cameras." Complete specification. Hugh O'Donnell and William Clinton South.

Printing Apparatus.—No. 4,171. "An improved photographic printing apparatus." Elea Luboshey.

Apparatus.—No. 4,298. "Improvements in and relating to photographic apparatus." Felicien Blanpain.

Mr. W. B. SAMUEL, who makes a special feature of restoring faded or tarnished Daguerreotypes, asks us to state that he has removed from 87 to 103 Clapham Road, London, S.W.

Exhibitions.

BIRMINGHAM PHOTOGRAPHIC SOCIETY.

On Saturday, February 27th, the nineteenth annual exhibition was formally opened by the President, Mr. A. J. Leeson. The exhibition secretary, Mr. Lewis Lloyd, is to be congratulated on having got together an excellent show. It is quite above the average level in quality, and contains a greater proportion of large work than last year. It follows the prevailing fashion in being decidedly low in price, but here and there one comes across a sunny, breezy bit of work that refreshes one like a draught of fresh air in a stuffy room. One of the striking features of the exhibition is the high position attained by the lady members of the society, chief among them being Mrs. G. A. Barton, whose work is extraordinarily strong, but we cannot but feel that her reputation would have been still more enhanced by the exclusion of several of her twenty-one exhibits, especially No. 89, "The Singing Boy," which is deplorable in line and powerful as Mrs. Barton's work is, it lacks one peculiar quality, that indefinable essence known among painter-artists as "restraint," a quality always found in the work of another member, Mr. Cruwys Richards.

The west room is filled with a distinguished collection of seventy-four photographs by Dr. Grindrod, among which the fine portraits of H. A. Acworth, C.I.E., and Dr. Elgar are at once noticed. It is a very good "one-man show," but the prevailing low tone of most of the work becomes rather depressing after a time. Mr. Cruwys Richards shows three interesting prints in Nos. 183, 186, and 189. Gum prints in colours, they are clever and fairly successful, but we cannot call them "photographs in natural colours," and we cannot help feeling that if Mr. Richards had tinted his monochrome prints with a brush, he, at least, would have produced a better result with one-fiftieth of the trouble.

In the loan collection there are a few beautiful prints by Robert Demachy, some large dramatic landscapes by A. Horsley Hinton, some of Dr. Douglas English's exquisite "wee tim'rous beasties," and some excellent photographs of reptiles by Dr. Frederick Graves.

The judges, Messrs. W. R. Bland, Harold Holcroft, and R. Catterton-Smith (the last-named being the recently-appointed head master of the Municipal School of Art), have been lavish with their awards, and it is rather unfortunate that practically all the prizes have gone to work of the most dull and depressing character, and one wonders why one of the silver medals in the open class should have been given to an attempt to produce a sentimental picture called "The Awakening" (No. 264), by Mrs. Barton, in which we have a mother who might be a negress nursing an equally dusky baby, with badly drawn legs, while next to it is a vigorous, life-like bit of work by the same lady, "The Village Belle" (268). An equally depressing print (175), "A Storm at Sea," has also been awarded a silver medal; and this the value of the fine rendering of the waves and flying spray is greatly discounted by the introduction of an impossible ship in distress. "Eleanore" (189), by J. Cruwys Richards, is a dainty little print in colours, but not quite convincing. "The Watcher" (324), by the same clever artist, is extremely good, but the shadows seem unnecessarily black. "The House on the Marsh" (225), J. C. Warburg, is a huge "gum" in dirty green, in which the values appear to us altogether false. "A Silenced Highway" (201), Harold Burkinshaw, one of the most beautiful pictures in the exhibition, is a masterly rendering of a snow-covered road. "Norman Work a Contrast" (315), Rev. H. R. Campion, is a delicate print full of radiation and charm. "An Old Inn, Vitre, Brittany" (217), J. H. Brindley, deserves its awards, and is a rich print of an old plastered house, but the shadow, in the bottom left-hand corner, is a little weak.

One wonders why "The Approach to Newcastle" (256), Dr. Alf. Miller, a commonplace snapshot of some fishing-boats, has secured an award, while "Evening on the Nile" (182), Arthur G. Peck, well-nigh perfect in the arrangement of the composition of the boats with huge sails, and in its suggestion of the end of a day of blazing sun, has received no recognition whatever.

The two best portraits in the exhibition, "George Phoenix, Esq." (145), David Murray, and "Clover" (147), J. Cruwys Richards, have been passed over by the judges.

In the members' class the silver medal goes to Mrs. Barton's "The Madonna of the Rose" (49), a work far inferior to others by the same lady close by. "On the River" (24), P. B. Rider, a coarse black "gum" with a crooked horizon, secures a bronze medal; we hope this will not induce Mr. Rider to abandon those beautiful effects he secures in carbon of old buildings. "The Hill Path" (28), Harry Goode, is a very good bit of woodland scenery, but unnecessarily low in tone. "The Rosary" (69), Ivo F. Lewis, looks as if the lady was in the last stage of consumption and knew it. "A Portrait" (76), Mrs. G. Arbutnot, is a very dainty and delicate portrait of the Vicar of Stratford-on-Avon, but he appears to have donned a white coat for the photograph. The novices class has some remarkably fine work in it. The exhibition is not so rich in architecture as usual, and even those shown have the same lowness of tone even when they are intended to represent gleams of sunshine; a refreshing exception must be noted, however, in Mr. Greatbatch's "Chipping Campden" (231).

The exhibition will remain open till Saturday, March 5th.

LIST OF AWARDS.

MEMBERS' SECTION.

Silver Medal.—(49) "The Madonna of the Rose," Mrs. G. A. Barton.
Bronze.—(24) "On the River," P. B. Rider; (28) "The Hill Path," Harry Goode; (69) "The Rosary," Ivo F. Lewis.
Hon. Mention.—(50) "Repose," J. C. Batkin; (76) "A Portrait," Mrs. George Arbutnot.

OPEN SECTION.

Silver Medal.—(175) "A Storm at Sea," F. J. Mortimer; (189) "Eleanore," J. Cruwys Richards; (264) "The Awakening," Mrs. Barton; (324) "The Watcher," J. Cruwys Richards.
Bronze Medal.—(306) "Desolation," J. M. Whitehead; (225) "The House on the Marsh," J. C. Warburg; (201) "A Silenced Highway," Harold Burkinshaw; (315) "Norman Work—a Contrast," Rev. H. R. Campion; (217) "An Old Inn, Vitre, Brittany," J. H. Brindley.
Hon. Mention.—(185) "A Wind Sea," F. J. Mortimer; (256) "The Approach to Newcastle," Dr. Alf. Miller; (335) "On Cannock Chase," D. Murray; (331) "Evening," J. R. Capey; (299) "A Country Gentleman," Mrs. G. A. Barton; (127) "Miss Olive Heygate," J. Page Croft; (347) "Calliope," F. S. Marks; (222) "The Eastern Crypt, Winchester," W. A. Clark.

NOVICES, MEMBERS.

Silver Medal.—(381) "Reflections Deep," H. Gilbert.
Bronze Medal.—(378) "Cwm Enian," W. Partridge.
Hon. Mention.—(373) "Contemplation," T. Edward Silvester; (377) "At the Fountain," B. Shirley Smith; (394) "Solitude," Thos. Clarke.

WARWICKSHIRE SURVEY.

Silver Medal.—Rev. A. Corbet.
Bronze Medal.—Thos. Clarke.

LOCAL SOCIETIES' COMPETITION.

Silver Medal for best set.—Erdington.
Bronze Medal for best in any set.—(21) "A Lowland Farm," W. Smedley Aston.

Hon. Mention.—(1) "Landscape," J. C. Taylor; (22) "The Chaucer," W. Smedley Aston; (23) "Marguerite," W. Smedley Aston; (28) "Autumn," E. Welburn; (35) "The Thames, Ifley Mill," A. Gibbons; (39) "A Portrait," Geo. Carder; (32) "The Daily Round, the Common Task," A. Gibbons; (51) "The Alien," Miss L. Hanman; (52) "Sunshine After Rain," Mrs. H. J. Shepherd; (53) "Thoughts," Mrs. H. J. Shepherd.

LANTERN SLIDES—MEMBERS.

Bronze Medal.—W. A. Clark, A. G. Patterson.
Certificate.—P. T. Deakins, Ivo F. Lewis.

LANTERN SLIDES—OPEN.

Silver Medal.—Rev. E. T. Clark.
Bronze Medal.—W. A. Clark, Rev. W. R. Campion, F. G. Mortimer.
Certificate.—Robert Burnie, G. A. Booth, W. A. J. Hensler, Dr. Rodman.

CRIPPLEGATE PHOTOGRAPHIC SOCIETY.

The fifth annual exhibition of the Cripplegate Photographic Society was held on the 29th ult., and the 1st, 2nd and 3rd inst., at the Cripplegate Institute, Golden Lane, E.C.

A young society, as this is, can hardly expect its member's classes to compete successfully with those classes which are open to all the world; but the principal educational value of an exhibition lies in the opportunity it gives the members of the society holding it comparing their own work directly with that of acknowledged experts. Doubtless bitter disappointment often arises in the comparison, but to those who can take advantage of the lessons to be learnt there is the consolation that if the physic is nauseous its effect is benign. Many of the members of the Cripplegate Society evidently take the utmost pains to improve their work pictorially as well as technically, and that their efforts are not unavailing is proved by the steady advance that is shown in the members' classes of each successive exhibition. In the present exhibition, not only is the quality of the members' work better, but there is a considerable increase in number of frames sent in to the exhibition. In the landscape class for members we were surprised to find Mr. B. C. Wickison competing for a medal. Naturally he gained a medal; but is it not playing even the medal hunting game a little low for one of his calibre to set to work to capture prizes from such photographically youthful opponents. The prevailing craze for bromide enlargements was as strongly manifested here as elsewhere, and some of the most evident faults in the work were undoubtedly due to want of recognition of the particular conditions which must be complied with to achieve success. There were many pictures for instance which were excessively hard, apparently from the employment of negatives of unsuitable scale of gradation for bromide enlargements by artificial light, but on the whole the work was much more interesting than that shown in the same class at previous exhibitions. In portraiture and figure subjects the members' class showed quite a remarkable advance, and contained quite a number of pictures of notable good quality. "A Fisher," by H. Gordon Stollard, was excellently treated, and a portrait of a gentleman, by the same, in spite of some minor faults was more than usually successful. C. G. Lacey's portrait of a child was equally good, and "Asleep," by H. W. Coke, while not excelling in pictorial treatment, was at least a great improvement upon the usual amateur's attempt at the same kind of thing. Other exhibitors in the same class which included all subjects except landscape were H. E. Staddon, W. J. Appleby, H. V. Abbott and A. Rogers.

The open class for pictures, which had been previously medalled, as usual in a champion class, was not a particularly interesting one, the best known pictures were by P. W. Crane, J. H. Gear, N. Judge Graystone Bird, F. J. Mortimer, H. G. Stollard, and G. H. Capper. The portraiture class was not a particularly strong class; in fact it contained some very poor examples. Among the pictures which appealed to us most were "A Cavalier," by J. B. Johnson, "A Little Sunbeam," by R. S. Webster, "Deborah and the Smile That," etc., etc., by A. Marshall, and "The Blacksmith," by B. Bishop. A fairly large class of landscapes contained many interesting pictures. "Eventide on the Bure," by J. E. Latham, several mountain scenes by J. E. Gunston, "The Glow of Evening," and "Thistle-down," by B. C. Wickison, "Schwarzwald Peasants," by J. H. Gear, "View from Bankside," by G. H. Capper, "Weary they Wend their Way," by E. W. Taylor, "Woodland Waters," by C. Scull, and "A November Afternoon" and "On the Thames" by W. L. F. Wastell, and some fine wave studies by F. J. Mortimer particularly attracted our attention. A small class of architecture perhaps reached the highest average in quality of any. The trade exhibitors were The Photographer's Art Paper Company, of Thornton Heath, The Autocopyist Company, and Messrs. Burroughs, Wellcome and Co., A. and M. Zimmermann, J. Barnard and Son, and W. Watson and Son. The judges were Messrs. J. T. Ashby, H. W. Bennett, and Fred Hollyer.

The following is the award list:—Class A.—Champion Picture.—Gold Medal—F. O. Swaine, No. 14, "Morning Service." Honorable Mention—P. W. Crane, No. 2, "Crypt de l'Aquilon." Class B.—Champion Slide.—Gold Medal—John Gunston, "Lake Brienz." Class C.—Portraiture.—Gold Medal—Withheld. Silver Medal—A. Marshall, No. 64, "The Smile that, etc." Bronze Medal—C. Treasurer, No. 70, "Man's Head." Bronze Medal—Miss M. Woods,

No. 44, "Study of a Boy." Class D.—Landscape, etc.—Gold Medal—John H. Gear, F.R.P.S., No. 102, "Schwarzwald Peasants." Silver Medal—John Gunston, No. 82, "Mer de Glacé." Bronze Medal—W. L. F. Wastell, No. 162, "A November Afternoon." Honorable Mention—John Gunston, No. 83, "In the Gorges of Trient." Class E.—Architecture.—Gold Medal—Alfred T. Ward, No. 176, "And all Below is Strength." Silver Medal—S. C. Stearns, No. 185, "Across the Nave, Winchester." Bronze Medal—John H. Gear, F.R.P.S., No. 172, "St. Mark's, Venice." Honorable Mention—W. L. F. Wastell, No. 186, "Altar Tomb, Cobham." Class F.—Lantern Slides.—Gold Medal—W. A. J. Hensler, "The Woodman." Silver Medal—John Gunston, "Mer de Glacé." Bronze Medal—F. J. Mortimer, No. 4.

Members' Classes.—Class G.—Landscapes, etc.—Gold Medal—B. C. Wickison, No. 189, "An Autumn Morn." Silver Medal—W. J. Appleby, No. 214, "After the Rain." Bronze Medal—G. H. L. Jackson, No. 230, "Down a Leafy Lane." Class H.—Any Subject not included in Class G.—Gold Medal—W. J. Appleby, No. 238, "Soapsuds." Silver Medal—H. Gordon Stollard, No. 267, "Repairs." Bronze Medal—C. G. Lacey, No. 262, "Portrait of a Child." Class J.—Lantern Slides.—Silver Medal—G. H. King, "The Valley Stream." Bronze Medal (extra)—A. T. Ward, "Little Cloister Passage, Gloucester." Class K.—Any Subject.—For Members who have not previously taken an Award.—Bronze Medal—J. B. Parrish, No. 289, "Near High Beech."

FORTHCOMING EXHIBITIONS.

March 5.—South London Photographic Society. W. Calder Marshall F.C.A., 41, Glenton Road, Lee, S.E.

March 5-12.—Brechin Photographic Association. Hon. Secretary J. Kirk, 1, Infirmary Street, Brechin.

March 8-9.—G.E.R. Mechanics' Institution (photographic section) Hon. secretary, A. Woolford, 16, Grove Green Road, Leytonstone.

March 9-12.—Nottingham Camera Club. Hon. Secretary, Arthur Black, 9, Bowers Avenue, Nottingham.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 22 to April 5.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

May 11-18.—Plymouth Photographic Society. Hon. Secretary Wilfred Grist, 105, Old Town Street, Plymouth.

DEVONPORT Camera Club.—An exhibition in connection with the above will be held from May 24th to 28th. Last day for receiving entry forms, May 12th. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

ADAM HILGER, Limited.—This company has been registered with a capital of £10,000 in £1 shares. Object, to adopt agreements with Mrs. Anne E. S. Hilger and F. Twyman to acquire the business of an optical and astronomical instrument maker, carried on at 75a, Camden Road, N.W., as Adam Hilger, and to carry on the same and the business of, makers of, and dealers in telescopes, spectacles, field glasses, eye-glass guards, and chains, spectacle cases, compasses, barometers, thermometers, and optical, astronomical, electrical, chemical, nautical, photographic, surgical, and scientific apparatus etc. No initial public issue. Mrs. A. E. S. Hilger is the first director, and may retain office while holding a quarter of the shares acquired by her under the purchase agreement. If J. A. Hilger should become director he may retain office while qualified. Directors' qualification £200. Remuneration as fixed by the company. Registered office, 75a, Camden Road, London.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
	Plymouth Photo. Society	<i>The Life and Work of Mr. A. Horsley Hinton</i> , Illustrated. Mr. Chas. H. Dymond.
	Ashton-under-Lyne Photo. Soc.	Chess Match, "B" League, Stockport 2nd. home.
	Aberdeen Photographic Assoc.	Lecture, Mr. Fred. W. Hardie.
	Glasgow & W. of Scotland P.A.	Exhibition Closes.
to 12	South London Photo. Society	Fifteenth Annual Exhibition.
	Bowes Pk. and District Ph. Soc.	Competition. <i>Interiors</i> .
	Burton-on-Trent Photo. Soc.	Members' Enlarging Night. <i>The Use of Bichromate Salts in Photography</i> . Mr. Edwards.
	Ilford and District Photo. Soc.	Affiliation Prize Lantern Slides.
	Glasgow & W. of Scotland P.A.	<i>Photomicrography</i> . Demonstrated. Mr. Rob. Garry, B.Sc.
	Southampton Camera Club.....	<i>A Photographic Tour Round the Isle of Wight</i> . Illustrated. Messrs. Geo. R. Johnson and A. C. Berry.
	Glasgow Southern Photo. Assoc	<i>Further Notes on Composition</i> . Mr. J. W. Eadie.
to 12	Nottingham Camera Club.....	Exhibition.
	Cricklewood Photo. Society.....	<i>Landscape Photography</i> .
	Everton Camera Club	<i>Bromide Enlargements</i> . Demonstration. Mr. J. F. Wilde.
	London & Prov. Photo. Assoc.	A Paper by Mr. A. Haddon.
	Watford Camera Club	Lantern Evening. <i>Amateur Photomicrography</i> . Prize Slides.
	Liverpool Amateur Photo. Asso.	<i>Photography Prize Slides</i> .
	Richmond Camera Club.....	<i>Northamptonshire Church Architecture</i> . Mr. J. F. East.
	Woolwich Photo. Society	<i>Some West Country Scenes</i> . Mr. J. Northwick Pauling, F.R.P.S.
	Hull Photographic Society	V. P. U. Invitation Folio.
	Gainsboro' Camera Club	Print Exhibition by Club Members.
	Aberdeen Photographic Assoc.	<i>Artificial Light Photography</i> . Mr. J. Milne.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

FEBRUARY 25TH.—Mr. J. W. Hodges in the chair. A vote of thanks was passed to Mr. Welford for his gift of a set of convention slides portraits of photographic celebrities. A paper was read by the hon. Recorder, entitled "Up-to-Date Photography," in which was advocated the catering for a large portion of the community prevented present from being able to patronise the professional photographer, the establishment of studios fitted with artificial light, and also the adoption of quick printing methods for prints, so that orders could be completed in hours, instead of days or weeks.

A very animated discussion took place, but the principal point was scarcely touched, the main lines taken being the admitted facts at professional photography of the present day was not a great success, and that the great majority of photographers took far away to long to execute their orders.

The Hon. Secretary and Mr. T. K. Grant were heartily thanked for their services in connection with the supper and entertainment.

PHOTOGRAPHY UP-TO-DATE.

Amateur photographers, as a general rule, are up-to-date in plates, paper, in apparatus, in methods, and in procedure. Process and plate photographers are also quick to embrace opportunities of progress, but the average portrait or professional photographer moves very slowly, indeed, the sole idea of the majority of professional photographers seems to be that the only way of being up-to-date is to cut down prices a shade below his rival over the way. Snooks and Co. will advertise 12 cabinets for 5s., guaranteed to be permanent and finished in the best West-end style; Jones goes one better, and offers in a 12 by 10 enlargement finished in black and white, and mounted in a handsome gold frame. One photographer advertises artistic portrait postcards at 4s. per dozen; next day his rivals in the same road offer them at 3s. 6d. and 2s. 6d., and in one case I saw exhibited a sample of dirty, fly-blown specimens called "the latest artistic novelty," 12 postcards for 2s.; two positions, 2s. 6d.

All this sort of thing indicates an utter want of business method, and also the frantic bidding for the patronage of a limited supply of customers, and all this in the face of the fact that passing their doors continually is an unlimited quantity of customers willing and able to pay good prices for good work, but who are absolutely neglected, viz., the great army of workers, male and female, who cannot spare the time, or get the opportunity, of being photographed simply because no provision is made for anyone who cannot attend during the ordinary working hours, i.e., in daylight.

Of course, as a pure matter of photography, portraits taken in day-

light may be the best, but as a matter of business, just as good results can be obtained by artificial light, and it must be better policy to cater for customers who at present have no chance of becoming patrons, than to cater for people whom you can only induce to patronise you when the charges are such as to leave little or no margin for profit.

In the "Photographic Chronicle," in October, 1903, was published an article by myself indicating the general lines upon which such a business could be carried on, and, given such an establishment, there would be no doubt as to its ultimate success. That the idea is feasible admits of no doubt, because at the present time the photographer has ample choice as to methods of lighting: incandescent gas, acetylene gas, arc or incandescent electric installations are all advertised, and each has its possibilities, advantages, and disadvantages. For success, artificial lighting must be continuous, not just turned up for the moment, and for this reason flashlights, etc., are not of the nature suitable for studio work. Such studios must be open at a later hour than is now customary, but that can be met by commencing later in the morning. With artificial light, P.O.P. can be discarded, and prints made upon bromide, or slow contact paper, matt or glossy, and with proper installation the orders can be delivered within twenty-four or thirty-six hours after the sitting. To do this is merely a matter of detail routine, and would not entail a larger staff than is at present necessary in an ordinary establishment. The operator would pose and expose, the developer would see the negative through, and deliver it to the retoucher, from the retoucher it would go to the printer, who would have no difficulty in printing a dozen copies all alike in, say, an hour, and delivering them to the mounter, who would not take long to mount and dry them; with ordinary care, very little spotting out would be required, so that allowing an hour in the developing-room, an hour with the retoucher, printer an hour, mounter an hour, spotting and packing another hour, so that six hours after sitting the whole of the copies should be ready for delivery. Such a scheme as this will to many seem absurd, simply because where I have indicated minutes the ordinary photographer allows days, except in the printing-room, where the days often get into weeks; but let the scheme be thought out and it will be seen that it is quite feasible, given the proper organisation, and keep the staff each to their own work, then there will be no doubt as to its success.

W. D. T. WILKINSON.

RICHMOND CAMERA CLUB.

FEBRUARY 25TH.—The meeting was devoted to a discussion on "The Right Process for the Right Negative." The subject was opened by Mr. Oetzmann, who, in an interesting speech, remarked that the beginner invariably commenced his printing operations with the paper known as P.O.P.—the most difficult and most unsatisfactory process that he could adopt, especially when the combined toning and fixing bath is used, but the most satisfactory for the manufacturer. The general result is nine unsatisfactory prints out of every ten, and the tenth probably faded in a month. Better results were obtained in the old days of albumenised paper, because photographers took the trouble to work and wash the prints with the greatest care, and made strong negatives, which, by slower printing, caused the print to sink deeper into the albumen than with the modern thinner negatives and gelatine paper. Nowadays, comparatively few amateurs take the necessary trouble, everyone choosing what he considers the easiest process, and, consequently, results are generally unsatisfactory. Mr. Oetzmann considered that with but little exception, all printing processes could, with proper care, be used with almost any kind of negative, unless it were hopelessly bad. Few men can produce exactly the quality of negative that they desire, but every man should make himself acquainted with all printing processes, so that he may be able to select the one most suitable for the object he has in view. The platinotype process is far superior to P.O.P., but the carbon process is the most satisfactory in its results, and the cheapest. It affords the greatest range of shades and colours, is absolutely permanent, and is very easy to work. Mr. Oetzmann showed a number of excellent prints both in platinotype and carbon.

SOUTHAMPTON CAMERA CLUB.

FEB. 29, Mr. Wm. Borrough Hill in the chair. A lecture, entitled "Seascape Photography," was delivered by Mr. F. J. Mortimer, the well-known expert on the subject. He confined the discourse to his

labours on the rugged Cornish coast, especially the Scilly Islands, to deal with the study of the monster breakers so abundant in that locality. Mr. Mortimer not only portrayed these by the aid of numerous lantern slides of a highly-meritorious character, but gave those present his personal experience in an unstinted manner, and the various useful hints as to the method of procedure, wearing apparel, and the most suitable plate and apparatus to use, being very much appreciated by his audience. The Chairman, in proposing a vote of thanks, spoke in eulogistic terms of the lecture it had been the pleasure of himself and the company to listen to that evening. This was seconded by Mr. Kimber, the Hon. Sec., who referred to the part Mr. Mortimer, as Hon. Sec. of the Southsea Photographic Society, had taken in the promotion of the combination exhibitions of recent years between the Hove, Southampton, and Southsea Societies, which had proved so highly satisfactory. This had been due in a great measure to the personal influence and prestige of Mr. Mortimer, with prominent figures in the photographic world, and he was sure that it would be regretted by all to hear that Mr. Mortimer was giving up the Secretaryship of the Southsea Club. Mr. Sargent, the Hon. Sec. of the Hove Photographic Society, in supporting the proposition, reciprocated all that Mr. Kimber had said, and hoped that Mr. Mortimer's successor would still continue the good work in connection with the exhibitions, and added that he was glad to see the enthusiastic and optimistic spirit so prevalent in the Southampton Club, which it always gave him pleasure to visit. The vote of thanks was carried with acclamation.

Commercial & Legal Intelligence

BRITISH Biotype Company, Limited.—The above-named company has been registered with a capital of £5,000 in £1 shares. Object, to acquire an invention for improvements in coin fed photographic apparatus; to adopt an agreement with the Biotype Company, Limited, and to carry on the business of photographers, chemists, engineers, wood-workers, printers, stationers, merchants, manufacturers, purveyors of any commodities by means of automatic apparatus or otherwise, etc. No initial public issue. The first directors (to number not less than two nor more than five) are T. W. Horton, P.C. Skelton, and J. C. Stephens. Qualification 100 shares. Remuneration (after 5 per cent. dividend has been earned) £150 each per annum. Registered office, Library Chambers, 13-14, Basinghall Street, E.C.

Re GEORGE RICHARD KNIGHT, 63, Castle Road, Southsea, dealer in photographic apparatus.—The above-named debtor appeared for his public examination at the Portsmouth Bankruptcy Court on February 29th, before the Registrar, Mr. Renny. The statement of affairs disclosed liabilities amounting to £778 4s. 11d. In reply to questions put by the Official Receiver, the debtor stated that the cause of his failure was paying his father's debts, which absorbed his capital, and to buying too heavily for the Christmas trade, which was this year a failure. He took over his father's business in Middle Street, which was insolvent, and the deficiency more than absorbed his capital of £100. Debtor admitted that he had overbought, at the late Christmas season, but had it been otherwise he would have made a good turnover. The examination was closed.

BEFORE the Registrar, at the Bradford County Court, on Wednesday, Alfred Halliday Jackson, engineer, lately residing at Ivy Road, Moorhead, Shipley, came for his public examination in bankruptcy. The debtor's statement of affairs showed that he estimated his liabilities at £4,304, and his assets at £2,860, leaving a deficiency of £1,444. He attributed his insolvency to law costs and losses in connection with the promotion of certain companies. He joined Mr. R. Hope Brown in the purchase of Coe's Collo-type patent for reproducing copies of photographs. They agreed to give about £5,000 for that patent, but the inventor did not carry out his contract. Arrangements had been made to have the affair exhibited at the Glasgow Exhibition, and space was allotted for the purpose. The inventor, however, failed to have the machine ready in time, and the agreement fell through. About £500 would be spent on that affair. A writ was issued for the return of the deposit with damages. The deposit was returned but he got no damages. Later he floated the British Empire Manufacturing Company with the object of speculating in specialities by advertising. The

specialities were sewing machines and household goods. That company was in liquidation now in consequence of an action by the Singer Manufacturing Company in the High Court. The British Empire Company were describing their machines as made on the Singer system, which they thought they were entitled to do. The judge refused to grant application of Singer's Company for an injunction; but they brought another action and won, the British Empire Company being restrained from describing the machine as made on Singer's system. Mr. King was appointed liquidator, and the liquidation was still proceeding. He could not say whether any dividend would be paid. He estimated his loss in connection with that company at £500. On the application of the Official Receiver the examination of the bankrupt was adjourned.

THE Eastman Kodak Company got a favourable ruling recently in the proceedings instituted against it by Hastings and Miller for alleged violation of Chapter 690 of the laws of 1899, known as the Donnelly Anti-Trust Act, and Section 168 of the Penal Code. Mr. Hubbs, attorney for the Eastman interests, retained Delancey Nicholl, Nicholl, Anabel, and Lindsay, as counsel, and also M. B. Phillips, who has been the patent counsel of Mr. Eastman for fifteen years. District-Attorney Jerome appeared for the people, with his assistants Mr. Hart, and Samuel H. Evins, of the firm of Blandy, Mooney, and Shipman. Mr. Evins is attorney for the Anthony Seville Company, the principal competitor of the Eastman Company, and it was admitted in the hearings that the law firm first appeared for Theodore Hastings and Harry G. Miller, the complainants, when this proceeding was initiated. The following is Justice Wyatt's memorandum: "This proceeding pending before me, sitting as a magistrate, was brought against the defendants to hold them criminally liable for monopolising and attempting to monopolise the business of making and vending photographic supplies in the State of New York and throughout the United States. The complainants in their charge against the defendants proceed both under the so-called Donnelly Act, which took its final shape by the action of the Legislature in 1899, and under the section of the Penal Code in regard to conspiracy in restraint of trade. Complaints allege as criminal acts the formation of the companies by making the New Jersey company the holding corporation, and also that the manner in which the goods of the defendants were sold was in restraint of trade. In regard to the formation of the companies, after a very careful examination of the authorities and on all the evidence in the case, I am brought to the conclusion that the defendants' proceedings in regard to the organisation of the companies were entirely in accord with the statutes of the State of New York and the statutes of the State of New Jersey, and it must follow, therefore, that their acts cannot be criminal. It also should be considered that this combination was not a combination of corporations competing in the same line of business, but the various companies which the defendants are composed were manufacturing and selling not similar goods. As to the second charge—viz., the so-called credit agreement which the complainants allege, all dealers with these defendants were compelled to accept, after a careful examination of the leading cases on the subject, taking in particular the case of Park v. The National Druggists' Association, and the case called the Strauss Case in 35 App. Div. Reports, I cannot find that such agreements can be said to be in any way in restraint of trade, or as at all begotting monopoly. The goods sold by the defendants were their own goods upon which they either had patents or were manufactured under secret process, and they were entitled and had the right to sell them in any way that they thought best. It follows, therefore, that the motion to dismiss the complaint and discharge the defendants must be granted. The defendants are discharged."—*"Rochester Democrat and Chronicle."*

At Clerkenwell Sessions, on Thursday last week, before Mr. M'Connell, K.C., a deformed man, named William Morrison Crouch, 47, artist, was indicted for having obtained by false pretences £5 from Alfred Gregg Cooper, £21 from Edward Fuller Cripps, £20 from Edward Krebser, £100 from Wm. Wardle, £36 15s. from Fanny Elizabeth Montfort, £30 from Esther Margaret Blythe, £50 from Robert Clark Williamson, and £3 from Charles Edward Carpenter, in each case with intent to defraud; the prisoner was also accused of incurring debts and liabilities by fraud. Mr. Guy Stephenson, for the Treasury, said that the prisoner was indicted for obtaining a total sum of £317 in connection with a photographic business at 22c, Ebury Street, Westminster. The method he adopted was to insert advertise-

ts in various newspapers offering situations to assistants and re-
ring pupils. The important part of the advertisements was that a sub-
stantial premium was required in each case. It was alleged by the prose-
on that the scheme was one highly dishonestly arranged to put large
s of money into the prisoner's pocket. The prisoner carried on the
svenor Studio, under the name of Beethoven, and he guaranteed
licants constant employment and claimed to teach photography
all its branches. In November, 1902, the prisoner took an unfur-
ned flat at Ebury Street, S.W., at a rental of £105 per annum, and
red into possession in January of last year. At that time he had
lung left Bexhill-on-Sea, where, said counsel, he was hopelessly
lvent. At Bexhill he had conducted a photographic business at
7 Sea Road, but it was not a flourishing one, a lady, named Jecko-
who had advanced Crouch £85, eventually taking it over. His
king account then had the large balance of one penny, and another
unt opened with £36 had dwindled to 4s. 5d. Crouch pro-
ded to engage assistants and take pupils, but for some time there
not even a camera in the studio, and when he was put in there
e no customers, so the employees occupied their time in photograph-
one another. On occasions some ladies called. These, however,
counsel, were no doubt of such attractive beauty that they were
tographed without charge. In short, the prosecution urged there
no real business, but Crouch continued to "engage the services and
" of operators in return for substantial premiums down to the
umn of last year. Then, continued counsel, the scheme was too
gerous to be proceeded with further, and he changed the premises
the quarters of a business transfer agency and employment bureau,
taking premiums from clerks and secretaries, who found their
es to consist principally of taking half-crowns as registration fees
o other applicants. About £133 worth of furniture was supplied
Messrs. Norman and Stacey for the "businesses," and only £36 was
e. Money was also owing for cameras and photographic materials.
ne case goods supplied were recovered by distress warrant. He
a great number of judgment summonses, unpaid accounts, to the
unt of £250, and a lot of finely printed notepaper used in the
ness. His assistants received only a portion of their salaries, and
they received came out of the premiums which they paid. Mr.
e, for the defence, after consulting with the prisoner, said that as
sult of counsel's opening statement, Crouch recognised that there
nothing else to do but plead guilty to incurring debts by false
ences in the cases of Cooper, Wardale, and Williamson to the
unt of £200. Mr. McConnell, K.C., said that in some of the cases
people had probably invested their all, and that was the worst
ng, showing that Crouch had a disregard for the interests of others
ong as he profited. He had been in custody six or seven weeks,
would be kept in the second division for five months.

News and Notes.

MEETING of the National Photographic Record Association will be
at the Midland Grand Hotel, St. Pancras, on Wednesday, March
Afternoon tea will be served at four o'clock. A report will be
ented and a discussion invited upon record work, and a collection
ir J. Benjamin Stone's more recent work will be exhibited.

RADIUM BANQUET.—The Technology Club of New York city
ntly held a radium banquet, in which the health of the Massa-
etts Institute of Technology, of the alumni of which the associa-
is composed, was drunk in "liquid sunshine." The lights were
ed, and Lester D. Gardner began the radium display. Mr.
ner showed a diamond which glowed when excited by the presence
bit of radium. He showed kunzite, excited under the same
itions, and then held up a tiny tube, of which he said: "I hold
y hand a minute portion of pure radium; it is difficult for you who
a few feet away from me to see the small particles in the glass.
e are in this tube twenty-five milligrammes of radium bromide
an activity one million times as strong as uranium. One gramme
his radium would cost 15,000 dols. and one pound would cost

approximately 8,000,000 dols. In the world all of this radium in exist-
ence could be placed on a twenty-five cent. piece, and therefore we have
before us the rarest specimen of mineral on the earth. With this I
intend to excite into luminescence diamonds, willimite and esculin." Mr. Gardner then produced a dancing skeleton and other objects
which had been coated with phosphorus paint, which, he said jocularly,
had been impregnated with an infinitesimal quantity of radium to make
its radiance permanent. Said Mr. Gardner: "I now call your atten-
tion to radium paint, so called. This is merely a new form of our
old friend luminous paint. It has been found that radium exceeds
it in luminosity, and when radium can be manufactured in commercial
quantities there is no doubt that a production properly called radium
paint can be made.

THE Allotropy of Metals.—When first used in a chemical sense,
allotropy connoted the property of certain substances whereby they
could assume, under appropriate conditions, a state differing materi-
ally from the form in which they customarily existed. The textbook
illustrations of sulphur in its various modifications—the octahedral,
the prismatic, the amorphous, and the dubious black and more-
dubious blue; phosphorus: colourless, red, and possibly scarlet;
carbon: transparent, hexagonal, and non-crystalline; of the red
and yellow varieties of mercuric iodide, and of the reguline and
powdery forms of tin—are in everyone's mind. It is intelligible
enough that the idea should be extended to other cases where differ-
entiation between two possible forms of the same kind of matter is
less easy. Without diving too deeply into antiquity, it may be said
that the belief in the frequent occurrence of allotropy in metals,
and in the ease with which change from one form to the other
might be brought about, arose with the systematic study of the
influence of impurities on the mechanical properties of pure metals
like gold and copper. Investigation found that very small quantities
of certain elements, such as antimony or bismuth, profoundly affected
the strength and tenacity of these materials, and as—at that time
no less than now—it could scarcely be supposed that these minute
quantities were capable of combining chemically with the whole mass
of the metal in which they occurred, the not unreasonable assumption
was made that their influence must be more subtle, and that, though
not uniting with the bulk of the metal, they were able to induce it
to assume an allotropic form. The conversion of white phosphorus
into red phosphorus is much promoted by the presence of a little
bromine. It may fairly be thought that the transformation of a soft
ductile metal like gold into a short brittle material may be caused by
a trifling quantity of some foreign element capable of changing, shall
we say, a gold into the β variety. Now, as long as this view was
confined to metals like gold and copper, in which the impurities were
either deliberately added for the purpose of the experiment, or were
adventitious, and recognised as so objectionable that the desire of
the refiner was to remove them with all convenient speed, the hypo-
thesis of allotropy was satisfactory enough, because no one cared
sufficiently about its truth to contest it. But when, in process of
time, it was extended to our chief industrial metal, iron, more earnest
attention—and attention from non-academic minds—was turned
towards the question. Broadly, the *ex cathedra* view about ten
years ago was that there were two kinds of iron—the ordinary soft
kind, called α iron, and a hard variety, called β iron. The latter
existed at high temperatures, and was resolved into the former as
the metal cooled. Hence hot iron was potentially hard, and if
arrested in the β condition by sudden cooling, would remain so.
The hardening of steel by heating and quenching was therefore
explicable. The characteristic impurity of iron—carbon—was invoked
as tending to inhibit the degradation of the β to the α form. With
proper modifications to meet several little hitches in its smooth
working, this hypothesis was serviceable, and even convincing; the
notion of allotropy had been successfully extended to the most difficult
and interesting of metals, belonging already to the list of structural
materials. There is a sound rule in the conduct of all inquiry; it
is to exhaust the obvious before examining the more remote of possible
causes. But the mind of man is so constituted that it leans constantly
towards the less obvious, and prefers an ingenious and plausible specu-
lation to the statement of humdrum observation. Hence, for some
time, allotropy was as fashionable as ions are now. When the afore-
said sound rule of pursuing and exhausting the obvious was put to
use, several things happened. In the first place it was found that

the peculiar quality of gold made brittle by trifling quantities of antimony was not due to any change in the gold itself, but to the separation of its grains by a matrix mechanically weak; that the same was true of copper and bismuth; that the same held generally for metals mixed with small quantities of materials which influenced their mechanical properties; that iron looked upon in the early days as pure contained quantities of impurities approaching 0.1 per cent., an amount relatively large; and that the structure of iron is profoundly influenced by inconsiderable percentages of carbon. In short, the whole situation was changed. Whereas the hypothesis of allotropy rested on the belief that the molecules of a metal or their grouping were altered by impregnation with some insignificant germ, inspection with so coarse a means as a microscope showed that the difference was molar—that there were great masses of stuff made up of the metal and of its hangers-on, stuck together, segregated, laminated, or what not, forming a complex structure the mechanical properties of which depended on the nature, quality, disposition, and mutual adherence of its constituents. Consequently, the idea of a hard kind of iron and a soft kind of iron naturally convertible is now chiefly of historical interest. One word of warning must be added. The failure of the doctrine of allotropy in the instances named to afford a tenable explanation in no way impugns its validity in other cases. Where a substance has been actually prepared in two or more forms, allotropy *ipso facto* exists; where it is merely deduced from a change of property, as in the case of iron, the whole question is one of hypothesis; when an hypothesis gets in the way of a fact it is bad for the hypothesis; thus it is only the hypothetical kind of allotropy which is now discredited.—“The Engineer.”

THE DECIMAL AND METRIC SYSTEMS.

To the Editors.

Gentlemen,—In my letter on this subject published on February 26th there are several mistakes that require correction. In the eighth line from the top the compositor has inserted the word “metrically” for “mentally” and spoilt the sense, while in the last few lines of the first paragraph he has left out all repeating points, and thus has very kindly afforded proof of my contention that such points often lead to blunders. The sums should be stated as follows:—

“The square of 21.142857, or of 12 083, or the products of .3 by .6, or of .16 by .09, or of .9317861, by 333.3.”

In the first line on page 179 “twenty-seven figures” should read “twenty-three figures.” This being a slip of my own, not the printer’s. Twenty-three figures includes the restatement of the sum, which is generally necessary with long decimal quantities, though not with duodecimal measurements. If the restatement is excluded, fifteen working figures are still required, as against only six with the duodecimals.—Yours, etc.,

C. WELBORNE PIPER.

February 26th, 1904.

INTERNAL REFLECTIONS IN CAMERAS.

To the Editors.

Gentlemen,—In your article on this subject you refer to the ineffectiveness of red cloth as a lining for cameras, but do not mention the use of orange paper. The following experience seems to suggest that this would be more efficient than the usual dead black. Some time ago I found a great difficulty in securing white margins on enlargements produced from a certain masked negative, the trouble being due to the fact that as the mask had to be very narrow on one side of the negative, light reached the edge of the rebate of

the carrier, which showed up distinctly on the margin of the enlargement. All kinds of dead black failed completely to stop reflections, even though I cut away the reflecting surface to a minimum, and the only perfectly successful remedy was lining the rebate with orange paper of the kind used sometimes for backing plates. The reflections were of course much more readily visible with orange paper, but they had no effect at all upon the rapid bromide paper used. Considering that these reflections were focussed by lens on to the enlargement, whereas the light reflected within camera is more or less scattered, it would appear that orange paper should be even more effectual as a camera lining than it proved to be in the particular case described. As wide-angle lenses are now too frequently used in hand cameras, it seems worth while to test the efficiency of a dull-surfaced orange paper lining.

As to the use of a lens-hood, I would suggest that this is best if rectangular; a circular hood cannot completely stop reflection. Yours, etc.,

C. WELBORNE PIPER.

February 27th, 1904.

NORTHERN PHOTOGRAPHIC EXHIBITION, LIVERPOOL.

To the Editors.

Gentlemen,—May I call the attention of your readers to the fact that all entry forms for the above must reach me not later than Saturday, March 12th, and that all exhibits, excepting lantern slides, must reach the Walker Art Gallery on or before Monday, March 14th. There can be no extension of time; the selecting and judging have been arranged for Tuesday, the 15th.

The exhibition promises to be of a very representative character, many of the foremost workers of the country having promised support, and I hope that it will be visited by many of the workers from outside Liverpool, and that any such workers will make themselves known to,—Yours truly,

C. F. INSTON, Hon. Sec.

February 25th, 1904.

THE BRENTFORD EXHIBITION.

To the Editors.

Gentlemen,—Following the action of the South London Photographic Society in extending the date of entries, as we are collecting exhibits from their exhibition, free of carriage, it is thought advisable to extend the date for receiving entry forms for the Brentford exhibition until March 10th, by which date pictures must also be received. The exhibition will be opened on Tuesday, March 15th, Mr. James Bigwood, M.P., and will remain open until the 17th inst. There are five classes in the open section in which silver and bronze plaques are offered as awards. There will also be a silver-gilt plaque offered for the best picture in the open section, irrespective of class. The plaques, manufactured to our own design by Mr. Restall, Birmingham, represent that picturesque portion of Brentford High Street, where stands St. Lawrence’s Church with its ancient tower which stood in the time of the battle of Brentford. This forms a very pleasing design worked in metal. Brentford is noted for its past, and is the scene of many events in history. Our plaques will become valuable, forming as they do a record of such an historic town which is being continually altered and modernised.—Yours truly,

FRANK H. READ.

February 29th, 1904.

ANNUAL DINNER OF THE PROFESSIONAL PHOTOGRAPHERS’ ASSOCIATION.

To the Editors.

Gentlemen,—I shall feel obliged if you will grant me space to remind members and those interested that the annual dinner of the Professional Photographers’ Association takes place at the Criterion Restaurant, Piccadilly, W., on Friday, March 11th, at seven o’clock. As this is entirely a social gathering we should particularly welcome the presence of professional photographers who are not members. We anticipate a large attendance and application should be made for tickets (6s. each) by Tuesday, March 8th.—I am, etc.,

WILLIAM GROVE, hon. secretary.

51, Baker Street, W., February 29th, 1904.

THE KODAK EXHIBITIONS.

To the Editors.

Gentlemen,—As we have been asked by the secretary of a Ramblers' Photographic Society whether it would be possible for him to arrange a visit of the members of his society to our exhibition of photographs of Japan at our Charing Cross Gallery, 40, Strand, W.C., as there may be other secretaries of clubs and societies to whom the same idea has occurred will you allow us to state:—(1) We shall all times be willing to arrange for special visits of parties and societies to our exhibition, and ensure them a cordial welcome. (2) Cases where the members of a society cannot visit the exhibition, Strand, within the hours when the gallery is usually open, we are happy to arrange to have the gallery opened at an hour most convenient to them. We need perhaps hardly add that there is no charge whatever to our visitors. Applications addressed to the manager at 40, Strand, will have immediate attention.—Yours faithfully,

KODAK, LTD.

43, Clerkenwell Road, London, E.C.

THE DECIMAL AND METRIC SYSTEMS.

To the Editors.

Gentlemen,—Your correspondent Mr. C. Welborne Piper attempts to improve my general statement that the calculation of most arithmetical problems is easier with decimals than with vulgar fractions. He seizes upon the example given by me not for proving that point, but for its simplicity and as a suitable illustration to a photographic audience, showing how a decimal fraction would stand as against a vulgar. To Mr. Piper's mind the case proves emphatically the contrary. It is an assertion without the proof, for to carry it out according to accepted rule on paper the one will require more figures than the other, which will emphatically prove what I stated to be correct, namely, that in general calculations by means of decimals are less figures than those carried out in vulgar fractions. Perhaps the method founded on some algebraical formula might be shorter, evidently the algebraical formula has to be found first, and when the multiplication of $6\frac{1}{2}$ by $4\frac{3}{5}$ might be accomplished without the decimal form of 6.5 by 4.75.

I had pointed out, we are told, later on, that fractions were unnecessary to the advantageous use of decimals I would have no more practical knowledge. This is entirely beside the question.

I was not teaching the L. and P. Association any arithmetic, I was illustrating the decimal system as a necessary preliminary to understanding and profitable use of the metric system. That is what I applied my practical knowledge, and in this point I was rebuffed by one member of my audience who knew more about the decimal system than probably the majority of those who visit photographic meetings. The next assertion by your correspondent that the great defect of purely decimal systems (most of them) is that they do not lend themselves to quick calculation. My reply is that to a mind not trained in decimal calculation it may appear so, and to a mind biased against a decimal system and in favour of the metric system they must be so, but once the prejudice is thrown off my contention stands good that generally the decimal calculation will require less figures, is less complicated, and simpler than one carried out with vulgar fraction or undecimally divided quantities; that most calculations of any magnitude or importance are always carried out on the decimal system more quickly with greater precision. In my own practice, without pretending to be an expert in calculation, I always convert all vulgar fractions into decimals, exactly contrary to what your correspondent asserts. Remarkable opinions which I hold about a duodecimal system are common, but I ignore the fact that we actually have a most invaluable duodecimal system by which we can multiply so and so better so and so.

It is quite easy to pick out a few figures in feet, yards, pounds or ounces, and vulgar fractions thereof, and put a sort of equivalent in inches or metric measurements against them, thereby trying to prove that the one multiplication is easier than the other. If I had said in my paper that it was easier to multiply say 120 cm. by 6 than its equivalent in inches—say 47½ ins.—by 6, I should have argued my own case most fatally, for the L. and P. meeting would

have laughed at me most deservedly; but that is exactly what Mr. Piper attempts to do with his example. It is hitting at the shadow and avoiding the substance. But I am anxious to learn all about the duodecimal system, which is so invaluable, and should it prove to be a superior thing to the decimal system and able to have evolved out of it a system of measures better than the metric system I should not stand out long, but should be one of its first converts. We have however first to learn what is meant by your correspondents' system, and if it be what we understand under a system, why keep it back? There is yet time while Parliament is deliberating upon the introduction of the metric system—the only rational system, according to Mr. Balfour. Let the duodecimal system be brought forward while it is time, so as to avoid the fatal step of committing ourselves to a system with so many faults, and having done so find it is too late and suffer accordingly the loss of a much better system. Perhaps Lord Kelvin, who does not care a dram for all the objections raised against the metric system, might yet become a convert to a better thing, and so would the writer when he sees it.—Yours faithfully,

J. R. GOTZ.

215, Shaftesbury Avenue, February 29th, 1904.

AMATEUR Photography at the World's Fair.—Hand kodaks may be carried into World's Fair Grounds without charge, the size 4 x 5 being the limit, and no tripods will be allowed with any size without a permit from the Division of Concessions and Admission. The rules regarding small instruments, coming under the head of hand cameras, have not been definitely decided upon. It is positive, however, that no camera requiring tripod will be permitted in the grounds other than those owned by the Photograph Concessionaires and newspapers and periodicals, which have special permits from the Concessions Department. At the Chicago Columbian Exposition hand cameras were allowed in the grounds provided their owners paid a fee of one dollar a day. There the kodak feature was under the control of the official photographer and he issued and sold the daily permits to amateurs. Here the concessionaire will have nothing to do with issuing permits for small cameras. Up to date, all cameras without tripods have been allowed in the grounds without charge. As to whether this will continue when the exposition opens lies with the Division of Concessions and Admission. It is probable that a fee will be charged during the exposition period, though this has not been definitely decided upon. An invitation is extended to all amateur photographers who come to the World's Fair city to visit the club room of the Missouri Amateur Camera Club, No. 1, North Broadway, for here is where you will meet your brother amateurs from all parts of the world. In the club room will be posted all the rules and requirements of amateur photographers who wish to take pictures inside the World's Fair Grounds. The register in the club room, we hope, will contain the names and addresses of every amateur photographer who visits the exposition.—"Professional and Amateur Photographer."

It may also be obtained from all Booksellers, Photographic Dealers and Railway Bookstalls.

Answers to Correspondents.

- ** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.**
- ** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.**
- ** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.**
- ** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.**

PHOTOGRAPHS REGISTERED:—

- F. H. Stanley, 6, Coton Road, Nuneaton. *Photograph of Dog Sitting in Chair Smoking Cigarette.*
- R. H. Shillito, Hereford Lodge, Cornwall Road, Harrogate. *Photograph of Painting of Virgin and Child.*
- A. M. Matthews, 5, Mount Pleasant, Manningham, Bradford. *Photograph of Snow Scene.*
- A. McHarrie, County Studio, Stranraer. *Photograph of the late Rt. Hon. the Earl of Stair.*
- W. C. Adams, 1, High Street, Witney, Oxon. *Two Photographs of Accident to Water Tower.*

TONING BROMIDES.—I. V. Y. writes: "In ALMANAC for this year, p. 1,077, re toning bromides, after fixing and washing well, I have toned them successfully, but the instructions given do not state if I am to fix them again after this toning. Please say." In reply: The prints need only be washed. They do not require re-fixing.

BLACKING LENS MOUNT.—A. COLLIER says: "I would be much obliged to you if you could give me a good recipe for a black (not reflecting) varnish for metal. How are interiors of lens mountings varnished?" In reply: The interiors of lens mounts are usually blacked with a thin solution of shellac mixed with lamp-black. Bates's dead black varnish is good for metal work.

PAPIER MACHE DISHES.—"PRINTER" asks: "Can you tell me how to mend papier mache dishes which are cracking (the layers of pulp parting) at the corners?" In reply: If the dishes are really broken, marine glue will probably be the best material to repair them with. If they are only cracked, or chipped, two or three coats of Brunswick black will possibly do the needful.

LENS QUERY.—GORDON McK. asks: "Will you kindly answer this question: What focus of lens is wanted to do the general work—i.e., portraits and groups—in a studio 16 ft. long?" In reply: For so short a studio you require (if you only have one lens) a lens of short focus with good covering power. For cabinet pictures one of 8 in. or 9 in. focus, of the anastigmatic type, with an aperture of F6, would be suitable.

STUDIO BUILDING.—H. D. RIDEN says: "I am going to build a studio, and should be greatly obliged if you would give me particulars of the best kind of studio to build." In reply: As we do not know the space at your command, or its surroundings, we cannot give any useful information. Better get Bolas' work on "The Photographic Studio: a Guide to its Construction, etc." That will give you the desired information. We do not reply to queries by post.

BROMIDE PRINTING MACHINE.—"QUERY" asks: "Can you kindly inform me who manufacture a bromide printing machine for doing bromide postcards in quantity? I have inquired from all the largest stock houses, but can get no information, as they know of no one who manufactures such an apparatus." In reply: Messrs. Marion and Co., Soho Square, if we mistake

not, supply bromide printing machines. Better communicate with them.

OBSCURING GLASS.—W. ROGERS AND Co. ask: "Do you know of any liquid mixture on the market, or can you give recipe to make a mixture that can be applied by brush or rag to make frosted effect on the clear glass of our studio windows sufficient to keep out sunshine?" In reply: We know of no such mixture on the market. White paint stippled on the glass will answer the purpose. Or flour paste, mixed with whiting, is also good and has the advantage that it can easily be washed off on the advent of dull weather when it is not required.

COLLOTTYPES.—W. SMITH says: "I have enclosed you nine postcards which have been done from my negatives, which are very fine negatives of brilliant quality and sharp in detail. Will you give me your candid opinion of the postcards? Are they half-tone blocks or are they collotypes? They are done for me as collotypes, and I have refused to take them as they are such poor cards. Have I been wise in so doing?" In reply: The prints enclosed are collotypes with a rather open grain. We cannot say whether they are wise or not in refusing to take them, as we do not know the price charged for them, and further, we have not seen the negatives to judge of their quality.

VARIOUS QUERIES.—"ANILINE" says: "I should esteem it a favour if you would reply to the following queries, viz.:—(1) Where can I obtain paper, photographically pure, and sufficiently stout for postcard purposes? (2) What dyes are most suitable for dyeing gelatine for orthochromatic filters, green, blue, yellow and red? (3) In the formula for sepia paper in the ALMANAC it says: 'After printing immerse in water, and then fix in 1-50 hypo solution.' How long should they be in fixing? (4) Are prints by this process as permanent as an ordinary silver print?" In reply: (1) Otto König, and Co., Cross Street, Finsbury, E.C. (2) Any of the coal-tar colours of the colour desired. (3) From five to ten minutes. (4) If produced with care, we see no reason why they should not be fairly permanent.

REGISTRATION OF NAME.—"BISCUITS" asks: "May I trouble you to give me your opinion as to what would be the best way to get about registering the name of a preparation for photographic I wish to make for sale? If I patent the preparation, I believe the method of mixing and chemicals would have to be declared would they not? Could you oblige me with the name of firm making cheap small bottles?" In reply: If you patent your invention you must publish the method of carrying it out. You can register a name as a trade mark under the Trade Marks Act. Then you need not say anything about the composition of the preparation. If you send to the Patent Office, Southampton Buildings, W.C., enclosing a stamp, they will send you the Trade Marks Rules, which will give every information. Small bottles may be had from Kilner Bros., King's Cross.

LENS QUERIES.—"INTERNAL REFLECTION" says: "I have read with much interest the article in this week's paper concerning internal reflection in the camera. Please reply to the following: (1) I am about to buy a 12 in. focus applanat lens, listed to cover at F8 a 12 by 10 plate, to use on a $\frac{1}{2}$ p. plate. Will such a lens be any more likely to fog the plate, if the bellows are dead black, than when I use the single combination (16 in.) of a 8 in. focus applanat? (2) When using a hood, as advised, to reduce the line of view, with a lens of large covering power, what is the best kind of hood to have, and how far should the project beyond the hood of the lens? (3) Should you consider that unpleasing or violent perspective should result from using an 8 in. lens on a $\frac{1}{2}$ p. plate? (4) Can you tell me the F speed number, according to Wynne's meter, of the Premo Film Pack the Ilford Rapid Isochrom plate, and Westendorp and Welmey Rapid Orthochromatic plate?" In reply: (1) Practically no, if the inside of the camera be dead black. (2) Blackened cardboard is as good as anything. Let it project as far as possible without cutting off the field of view. (3) Not particularly so. (4) No; we have not tested any of them with Wynne's tester. When you write again, please use a sheet of paper instead of crowding so much on a postcard.

EX CATHEDRA.

Szczepanik's colour process. At a recent meeting of the Camera Club of Vienna, Baron von Hübl gave a brief address on the "bleaching-out" process of colour photography, and specimens were shown by Dr. Neuhauss, Worel, and Szczepanik (which is, by the bye, pronounced Shepannik, as near as an English tongue can get). The first experiments in this direction were made by Vallot, but he was not very successful in consequence of the difficulty of finding dyes sufficiently sensitive to light. Neuhauss and Worel increase the instability of the dyes by sensitisers, spreads each colour film separately, and such as hydrogen peroxide, ammonium persulphate, etc., thus obtaining very sensitive films, which, however, can only be used on glass. Worel uses anethol, the crystallisable camphor of aniseed oil, which is practically the odorous or malodorous principle so easily recognisable in bath rock and cough lozenges, and is able to obtain super prints. Both these experimenters, however, make a mixture of the dyes, whereas Szczepanik, using the same sensitisers, spreads each colour film separately, and is thus able to equalise to a far greater extent the bleaching of the dyes. Von Hübl states that his paper gives very brilliant pictures and a good reproduction of greys, and expresses the opinion that this process in conjunction with coloured transparencies produced by three-colour printing, will be a valuable addition to colour photography,

and further that if the light sensitiveness of the dyes could be increased one thousand times, the problem of colour photography would be absolutely solved.

A New Incandescent Lamp. Photographers who can refer to the "Photographisches Wochenblatt" for the 1st of this month may see the illustration of a new incandescent lamp, the invention of Professor Drehschmidt. It burns petroleum, and gives a light equal to 2,200 standard candles. It has no wick, and may, therefore, be classed with the Kitson light. It differs from the latter in the construction of the generator, which is claimed to be more simple in the Drehschmidt lamp. The light is started by ignition of a small quantity of methylated spirit, and actuating a small air pump, worked by hand. When the lamp is warmed up sufficiently, it appears to require no more attention. A pressure-gauge indicates any variation, and a falling off in the light may be remedied by means of the air pump. If the lamp is well constructed and does all that is claimed for it, there should be plenty of scope for its use by photographers. Portraits have been taken by its light in from five to seven seconds, and collodio-chloride prints have been made in thirty-five minutes. It is therefore nearly comparable with diffused daylight. For enlarging and the exhibition of lantern slides it should be of great value. The mantles cost eighteen-pence, and last for one hundred hours' use. The cost of the petroleum is about one penny per hour.

* * *

The Danger of The "Daily Chronicle," one day last week, reported a serious accident through the use of a flash-light. It appears from the report in our daily contemporary that at the conclusion of a dinner at the Strollers' Club, New York, a flash-light photograph of the diners was being taken. The flash-light set fire to some of the decorations, and a panic ensued; the guests rose in fright to make their escape from the room. Many were knocked down and injured, one being stunned. This should serve as a warning to all who use flash-lights to see that the light is not fired anywhere in close proximity to inflammable materials. We have on several occasions seen flash-lights of an explosive nature fired dangerously close to inflammable materials, light curtains, and the like, the user not realising the danger incurred. Most of the flash-light compounds are of an explosive character, and evolve great heat in their combustion, which may set fire to any light material in their vicinity; also that it may not be noticed at the moment, as the intensity of the light for a time so dazzles the eyes that any smaller light is not for a time perceptible. There-

fore, this panic in New York should serve as a caution to all users of flash-lights, particularly in small rooms. We are frequently asked for formulæ for flash-light compounds, but are always somewhat chary of giving them for the reason that the majority of those who ask for them are unacquainted with their dangerous properties. In all cases when flash-light mixtures are made which contain oxygen-forming compounds, such as chlorate of potash, permanganate of potash, etc., the components should be dried and powdered separately, and kept separate, being only mixed at the time of using, and then only in quantities sufficient for a single flash, a strip of paper or cardboard being used for the mixing. If the ingredients are kept mixed together they are liable to go off spontaneously, and often when least expected; hence the source of many accidents.

* * *

Orthochromatism. We think there are notable indications that the orthochromatic plate will take a more prominent place in photography in the immediate future than has hitherto been the case. The fact, too, that manufacturers of these plates are devoting more attention to suitable screens for their special brands is one which cannot fail to induce the photographer to avail himself of colour sensitive plates. Everything which tends to promote their correct use must contribute to their ultimate success. We draw attention to this because we frequently see specimens of work done with screens accentuating the characteristics of the particular sensitiser, even to the point of error. A specimen of this kind may be seen in the last number of the "Photographische Mittheilungen," opposite p. 69. The photograph is by E. Terschak, of Cortina d'Ampezzo. In that locality the photographer has to contend with deep blue skies of Italian intensity. If the mountains were covered with snow at the time the photograph was taken, the contrast presented between the deep azure sky and the snow-clad rocks may be correct, but the foliage of some trees, near the foreground, is snowy white and provokes a smile when compared with the dark tones of the grassy slope upon which the trees stand. Photographers who use orthochromatic plates would do well to confine their attention to one brand, study its characteristics, and find the most suitable screen to use with it. They may otherwise find themselves committing mistakes as absurd as those they endeavour to avoid. Our manufacturers can do much to remedy the evil by sending out carefully-adjusted screens, and we feel certain it would be to their advantage to do this at a minimum price, as it would conduce to the sale of their plates. A good negative is the best advertisement for a good plate. Perhaps it is not out of place here to mention that a new sensitising salt called "Pinachrom" has been brought out by Meister Lucius and Bruning, of Höchst, a/M. M. Léon Vidal, in the "Moniteur de la Photographie," writes of it as being more sensitive to red even than Orthochrom T.

Photo Sculpture.

Some bas-reliefs in metal of very high quality were exhibited the other night at the Royal Institution. They aroused a good deal of interest because they were produced by a new photographic process, of which we will attempt to give a brief outline. We will suppose that it is intended to produce a profile head on a medal from the living subject. We presume that the face and head of the sitter would be powdered or whitened in some way, but this is a detail of which we have no information. An ordinary negative is taken of the subject, but under special conditions of lighting—that is to say, the lighting is, by means of lamps of special

construction, we suppose, split up into ten planes of diminishing intensity, the brightest plane illuminating the parts of the face nearest to the lens, or, in other words, the parts showing the greatest relief. Then, step by step, the lighting intensity is diminished, until at the background it almost ceases to be light. This negative is subsequently, by the intervention of bichromated gelatine, made to yield a mould in plaster, from which the final bas-relief in metal is obtained. Full details of the process will doubtless be forthcoming in the near future, but at present we are only able to give this bare outline, gathered from brief verbal description. That the process is a practical one is evident from the excellent examples shown, in which the head measured about two inches across, with a relief of about one-eighth of an inch. Should this process bear out its early promise, the artists and designers of coins and medals will have a formidable rival to face. It was much the same with the wood-engravers a quarter of a century back. At first they found in photography a most potent aid, for drawings could be reproduced to any scale and transferred to the boxwood block. Then all of a sudden photography stepped in and ousted the engraver altogether. If the die-sinker is dispensed with in the production of medals, coins, seals, and things of a like nature, it will cause a flutter in many a dovecot. But designers may take to themselves one little grain of comfort. A man is not generally appreciated until some time after he has gone over to the majority, at least, not sufficiently to cause medals to be made in his honour. The artist will still be required to shape the features of celebrities, so that posterity will know what they were like.

* * *

Star Shadows.

On a brilliant starlit night one can often see pictured in some still pool the image of those brighter orbs of heaven which for centuries have been the wonder of mankind. But it is seldom that any one of these distant bodies is bright enough to cast an appreciable shadow on the earth. Sir John Herschel notices this unusual phenomenon in his "Outlines of Astronomy." He says: "Under favourable circumstances Venus projects quite a strong shadow. This should be received on a white ground. The open window of a room with white walls is the best arrangement. In such a situation I have observed not only the shadow, but the diffraction fringes which border its contour." It lately occurred to M. Touchet, Assistant Secretary of the Astronomical Society of France, to try whether the light from Venus would cast a shadow strong enough to make its presence visible on a photographic plate after development, and the result of this effort to trap the planet's borrowed light has been eminently successful. He appears to have employed a long tubular camera, with a sensitive plate, in front of which was a suitable object to cast a definite shadow—the spring holder of an electric glow lamp. An exposure to the planet's light, to which the camera was pointed for fifteen minutes was sufficient to impress the plate, and the photograph, or rather shadowgraph, is reproduced in a recent number of the "Scientific American." Emboldened with this success, M. Touchet determined to make the still bolder attempt to photograph the shadow cast by one of the fixed stars, the distance of which, from our earth, is so inconceivably greater than that of the planets. He naturally chose for his experiment one of the most brilliant of those wondrous orbs—the blazing dog-star, Sirius. In this case the exposure was extended to a little more than an hour, but the shadow of a small object was secured upon the plate with equally good results. It might be thought that the diffused skylight would have somewhat interfered with this interesting ex-

periment, but, as a matter of fact, it was too feeble to need consideration. Sirius is believed to have a diameter equal to twelve times that of our sun, and to be at such a distance from us that if its light were suddenly quenched we should not become aware of the circumstance for a period of about nine years. That a source of light energy so distant should be able to cast a shadow is a remarkable thing to ponder upon.

* * *

Fees for reproduction. The circular on Copyright Notes, issued by the Photographic Copyright Union, which we reprinted last week, should be read by every professional photographer, and not only read but acted upon with unanimity. One of the very frequent queries we have to reply to through the Answers Column is: What are the usual fees charged to newspapers for the right to reproduce photographs in their pages? A fortnight ago we answered a correspondent who wrote asking what were the usual fees, adding that he had been in the habit of charging, for the cabinet size, five shillings, and other sizes in proportion. Our correspondent enclosed a copy of a letter he had received from a Manchester house, saying that his charges were exorbitant, and that they only paid two shillings for a cabinet picture and the right to reproduce it. Could anything be much more ridiculous than this? In a case like this, when the prices alleged to be charged by some are played off against the photographer, the suggestion made in the circular is very apropos—namely, to write to the one named, and ask if the allegation is correct or not. It will be seen that the minimum scale of fees to be charged by members of the Photographic Copyright Union, and those laid down by the Professional Photographers' Association, are practically identical, and they should be strictly adhered to by photographers generally, whether they be members of either Association or not. The fees are very moderate, and the newspapers are well able to afford them. Although these minimum fees are laid down by both Associations, it is distinctly pointed out that photographers can charge what they like above them, and, in many instances, much higher fees are charged and paid than those named as the minimum. In all cases when permission is granted to reproduce, whatever may be the fee charged, it should be stipulated that it is for the paper named and for no other, and for only one edition. It is no uncommon thing with the proprietors of a number of periodicals to pay the photographer for the right to reproduce a picture in one publication, and then use the block in one or more of the others. This should be guarded against in the way indicated, and further fees obtained, if the blocks are used in other papers, for it stands to reason that the more a picture is reproduced the less demand there will be for the original, more particularly if the reproduction is used for advertising purposes. There is one paragraph in the Photographic Copyright Union Copyright Notes that we would call special attention to just now, namely, that referring to the sale of rights to reproduce photographs for pictorial postcards. Many country photographers who publish local views selling at, say, a shilling, or in album form, who have sold the right of their reproduction as postcards for a small fee, have found to their cost that there is practically no sale at all for the original pictures. The postcards have destroyed the business. In such cases it is something like selling "a birthright for a mess of pottage." The Photographic Copyright Union suggest that the right for postcards should be granted only by way of royalty, the minimum fee being half-a-guinea per thousand for half-tone or collotypes, and a guinea per thousand for bromides

or ordinary photographic processes. We doubt, even at these small fees, if they will compensate the photographer for the loss of sale of his larger pictures. We would once more impress upon our readers the desirability of making every local view they publish copyright directly it is taken. The cost is so small that it is covered by the sale of a couple of prints, and then one has the "whip hand," and can recover substantial damages, penalties, injunction, etc., from anyone who infringes it in any form.

COPYING BY ARTIFICIAL LIGHT.

SOME little while ago there was an amount of discussion about the copying of pictures that might have led to important practical results if more attention had been given to it, and the end would have been of value, for it is evident that more and more of this class of work which might well be done at home is "put out." And the more thought that is given to the matter the more remarkable does this appear. In the old wet-plate days when a plate kept more than ten minutes or so before developing became subject of more or less anxiety as to its freedom from markings when developed, it would have been little wonder if the work were shirked, but as a general rule it was not. At the present time, with a plate ready prepared and which will not produce spots, stains, or comets, though it were exposed in the camera for a day, the work is shirked. Why this should be so is an enigma. The solution is probably a complex one. The photographer of the present day has not had the rigid training that was almost compulsory a generation ago. It is so easy to make photos of a sort, that anyone with a little capital and a little camera is ready to start a business, and, when started, he will find hordes of would-be assistants equally well equipped. Then again the whole tendency of modern life lies in the direction of specialising and going to specialists. Our grandmothers would have held up their hands in horror at the idea of purchasing even dainty dishes at a confectioner's; their degenerate grandchildren will furnish their table mainly with viands from outside. Almost everything is "put out"; so why should not photos follow the rule? The question for the photographer to study is not merely one of economy, though, with business in such a state, as it now unfortunately appears to be, it behoves everyone to be rigid in his requirements in that direction; it might be more justly termed one of expediency. The securing a commission will often depend upon the ability to execute it without delay. It should be a very simple matter to copy a picture "while you wait," and either deliver a print in an hour or two, or let the client take a valued original away, and receive his copy in the ordinary course of business; and it is here where the value of artificial light becomes manifest. Where such work is only occasional there may, even with experienced hands, be some difficulty in hitting at the first attempt the right exposure, with the result of considerable loss of time. When using artificial illumination, once the exposure, with a fast plate, and a uniform light, is found, it can be correctly repeated at any future time however distant, the only factor of doubt lying in the due appraisement of the colour of the picture to be copied, and little experience here would be needed. The main point to remember is that the distance of the picture from the illuminating centre must either be constant or the rule of the power of the light diminishing in the inverse ratio of the square of the distance must be rigidly adhered to. Another great convenience of copying by artificial light is that it can be carried on in any dark corner, spare room, or, best of all, in the darkroom itself

if there be space, and, with skilful management, space requirement can be reduced to very modest dimensions.

The choice of illuminant will virtually lie between gas-light and electric, the latter being preferable on many accounts. If gaslight be chosen, the products of combustion in a small closed room are injurious, even with an incandescent burner, so that its usefulness is more restricted. And, again, with incandescence the light is by no means uniform, the power of the light diminishing daily (or a week or two after a new mantle has been installed), and being liable to fluctuation, according to the condition of the mantle itself, difficulties which practice would readily overcome, but which yet remove the factor of absolute uniformity of conditions, which is the key to despatch. For this reason an ordinary fishtail burner is the most desirable to use, though its actinic power is so much inferior.

Electricity is now so generally laid on in most houses that it is usually available, and it practically forms a typically perfect and constant source of light. When the Cooper-Hewitt lamp gets into familiar use it will probably be generally adopted for copying purposes; but till that time arrives all that is necessary for casual work can be found in the common incandescent lamp, provided it be not worked after the bulb is darkened. The light is equally useful in that state, but the element of constancy is removed, as its intensity, and especially its actinic quality, become gradually impaired.

We have recently made some experiments in this direction, and we found that when copying an ordinary albumenised print to the same size we had no difficulty in obtaining an excellent negative in from ten to fifteen seconds, using F8 diaphragm.

We will now discuss certain points in the practical use of the lamps or other sources of illumination, in order to obtain the greatest success.

Where great economy of plant is paramount, a single lamp will suffice, and, suitably placed, will not bring out the "grain" of the surface in too prominent a manner; but if pictures larger than half-plate are being copied, the illumination will fall off a little on the side furthest from the burner. Two lamps are far better, one on each side of the picture to be copied. The grain of the print then scarcely shows; the duration of exposure is lessened rather more than two-fold; the illumination is even; a 12 by 10 can be copied to the same size without any apparent unevenness of lighting. They should be placed on each side, at an equal distance from the picture, and should be opposite its centre. Of course, more than two could be used so as to make the evenness of illumination almost mathematically perfect; but more than two are not really necessary, except with a very dark print to be much enlarged, or when copying a larger-sized original than 12 by 10. Remembering the rapid diminution of intensity of the light as it is removed from the picture, it should not be taken too far away, or the exposure will be unduly increased. Nine inches from light to picture will be a suitable distance. With F8 and two 32C lamps of ordinary intensity ten seconds will be ample exposure. It should be brought as near to the front of the picture as possible, consistent with avoiding reflections, though this is limited by a hard-and-fast line.

The light must be screened from the lens.

The camera front should be covered with a piece of black velvet or paper to avoid reflections, especially when photographing a glossy-surfaced original.

The further the light is removed from the picture to be copied the greater the distance it must be removed from a line joining centres of lens and picture, and, of course, the converse is true.

If the light is too near that line, there will appear on the negative at the edges of the print either actual reflections of our lamp, or foggy patches forming broken reflections. The method of avoiding this is to observe the image on the focussing-screen, or, more scientifically, to draw a line from one side of the picture to that side of the lens furthest from it (or to stretch a piece of twine), and then to make a second line starting from the edge of the picture and directed outwards, forming a V, this second line to be at the same angle to the surface of the picture as the first. The light must not come within the V.

If these instructions—the outcome of actual work—are well considered and acted upon, the copying on any scale, enlarged or reduced, will be rendered absurdly easy and expeditious, and the work will come to be a pleasure instead of a thing to be shirked.

ROYAL PHOTOGRAPHIC SOCIETY.—Mr. Harry Selby will give a lantern lecture, entitled "Rambles in Yorkshire Dales," illustrated by slides from his own photographs, on Tuesday, March 15th, 1904, at 8 p.m., at 66, Russell Square. (Ladies are specially invited.)

ROYAL INSTITUTION.—A general monthly meeting of the members of the Royal Institution was held on Monday afternoon (the 7th inst.), Sir James Crichton-Browne, treasurer and vice-president, in the chair. Miss L. A. Black, Mr. H. T. Davidge, Mr. H. F. Dickens, K.C., Mr. F. S. Eve, Mr. F. L. M. Forster, Miss C. E. M. Gibbons, Mr. T. G. Hull, Mr. Vivian B. Lewes, Mrs. Gerard Leigh, The Hon. Mary Portman, Mr. H. R. Prendergast, Mr. W. N. Shaw, F.R.S., Mr. J. Sorley, Dr. R. H. Scanes Spicer, The Hon. Sir Joseph Walton, and Mr. E. Wormald were elected members.

THE REPRESSION OF THE BRITISH INVENTOR.—Mr. W. S. Boulton writes to the "Journal of the Society of Arts" suggesting the reconsideration by the Society of Arts of the whole question of British Patent-law, "with a view to urging an alteration so as to make things smoother for the inventor, who, unless a rich or influential man (which almost always he is not), has difficulties and expenses enough in all conscience to contend with in the working out and introduction of his invention in a nation whose ideas of enterprise and honour are summed up in the following couplet, which I have more than once had thrown in my teeth as a reason for not trying something new:—'Be not the first by whom the new is tried, Nor yet the last to lay the old aside.' In other words, show no enterprise yourself, but when your neighbour has sunk money and undergone worry and anxiety in doing the pioneer work, pounce in and rob him of as much of his just reward as you can! A question that has long puzzled me, is: Why is there such an enormous difference in the laws of patentright and copyright? Patentees and authors are both inventors, and in each case the invention may be of great, little, or no value, and be the result of much or little labour and expense. Here, however, the similarity ceases. The author can place his invention on the market at a very moderate further expense; the patentee may be impotent to proceed until he has in some way secured the application of large sums of money. There can be little doubt that on the average it costs very many times as much to put a patented article on the market as to publish a book, and takes far longer. In view of this difference, how does the law help the patentee? It first gives him a good chance of losing protection altogether by 'publication,' before he files his application for a patent, and it then taxes him to the extent of £99—which in the aggregate produces, I think, over £100,000 per annum beyond the expenses of the Patent Office—in return for which it grants him a patent for the maximum term of fourteen years. The author, on the other hand, cannot lose protection by publication—in fact he thereby obtains it—and the fee to empower him to enforce his rights is 5s. Finally, his protection lasts about three times as long as a patent. In other words, the patentee has to pay for protection 1,188 times as much per annum as the author. Can any man say that this is just? Why should the patentee be charged so incomparably more than the author? Why should his protection be for only one-third of the copyright time? And why, in the name of all that is extraordinary, should publication in the one case prevent protection, and in the other be the means of procuring it?"

ELECTRIC SPARK PHOTOGRAPHY.

to those photographers who possess a fairly powerful induction coil or Wimshurst machine the study of the effect of an electric spark on the sensitive film of a dry-plate will afford a very interesting and instructive occupation. The writer gives here the results of some experiments in photographing that form of electric discharge generally known as a "spark." For these experiments an induction coil constructed for X-ray work, and giving a 10 in. spark, was used. An instrument throwing a long spark produces, of course, the most brilliant effects, and larger plates can be used to receive the impressions, but good results can easily be obtained with machines that only give a 3 in. flash. The experiments must be conducted in a dark room, in the day-time; the machine can often be conveyed to the photographer's dark room, but if this is not conveniently arranged for the purpose, operations must be suspended till after dark, when any room can be utilised for exposing the plates. An induction

Fig. 1.—Photograph of Electric Spark from Induction Coil.

coil is most convenient for taking spark photographs, as the operator, with this form of electrical machine, does not require assistance. With a Wimshurst an assistant is necessary to work the machine while the photographer makes the exposure. The best results are obtained in damp weather, as, in a moist atmosphere the spark throws out a greater number of radiations, and gives more varied and picturesque effects. The writer has obtained the best results in the dark room, as photographic manipulations keep the air moist. With regard to the best kind of plate to use, a rapid isochromatic emulsion is the most suitable; the slower brands tend to give excessive hardness to the image, and the finer details of the radiations are not so well defined.

There is no great difficulty in obtaining an impression of the electric discharge on a photographic film. If an induction coil is used, the dry plate can be laid on a box or pile of books immediately beneath the terminals of the machine. When the

current is switched on, the spark will generally be slightly deflected downwards and cross the plate, or portion of the plate, between the terminals. The word "generally" is used advisedly, as the electric spark does not observe any fixed rules,

Fig. 2.—Electric Spark. Plate held Perpendicularly to the Terminals.

and is a most uncontrollable factor in the case. If preferred, the plate can be held by one corner in the hand, while the exposure is being made, but the spark gives a rather unpleasant shock when it strikes across to that particular corner. The chief trouble experienced with the induction coil is the difficulty of rapidly switching the current on and off again. This operation should be performed in a small fraction of a second, or a series of flashes will cross the plate in all directions, and render it useless. The operator for the first few attempts is

Fig. 3.—Electric Spark, with Magnet on Plate.

very apt to work the switch too energetically, with the result that after making the contact the handle is brought too far back, and another circuit is made, and in consequence a second display of sparks spoils the plate. The best method of working

Fig. 4.—Electric Spark. Steel Wire laid across Plate.

the switch-handle is to turn it over towards one of its contacts till the circuit is nearly completed; the circuit can then be very quickly turned on and off again, as the handle has only to be moved about a quarter of an inch. When using a Wims-hurst machine the spark can be sent across the plate by swinging one of the terminals rapidly towards and past the other (which is kept stationary over the plate), a spark will then be sent across the film.

In taking spark photographs, the great object is to obtain an image which reproduces the numerous streamers or radiations proceeding from the track of the chief spark or series of sparks. These minor branches give a very striking appearance to the image, and form into shapes not unlike ferns or palms. An endless variety of picturesque formations is supplied by the electric spark, and every impression taken has its own peculiarities and beauties. The form and style of the sparks are altered to a large extent by the kind of terminals that are used, and the changes can be rung indefinitely on knobs, points, cups, and discs, as they all assist in giving variety to the images produced on the photographic plate.

It is not always an easy matter to get a brilliant spark just as the plate is placed ready for exposure, and several experiments should be made over a spoilt plate before an exposure is made. If an induction coil has been "sparking" for several minutes it is sometimes difficult to get a strong flash; in this case the coil should be "rested" for five minutes, and it will then be found to work more energetically. For developing the image, an energetic developer, such as amidol or metol, should be used, as the less exposed portions of the picture are more easily developed, and the contrasts between the dark and light portions of the image are not so harsh.

The first illustration shows the effect of an electric spark on the photographic film. It will be observed that the principal flash went in the direction of the thumb that was holding the plate; the thumb-mark is plainly visible. A fine number of streamers are sent off from the main line of the spark. In taking this picture the plate was held just below the terminal knobs.

In Fig. II. the plate was held between the terminals; the

Fig. 5.—Electric Spark. Iron Filings on Plate.

sh in this case struck the plate in the centre, giving off several "splashes" round the point where it came in contact with the plate. As a rule, when the plate is held perpendicularly between the terminals, the spark is conducted over the edges of the plate, but in this case the centre of the plate received the discharge.

Fig. III. shows the effect of laying a magnet on the plate. The magnet was placed obliquely between the terminals. The spark struck both ends of the magnet, and a thin white line down each side of the steel shows the path taken by the current. A steel wire was laid across the plate when the impression produced in Fig. IV. was taken. The wire intercepted the spark which ran along to both ends of the wire, branching out on each side.

Fig. V. is a reproduction of a plate on which iron filings

only plate in this series of spark photographs in which reversal occurs.

The writer tried the effect of soaking the plate for a few seconds in a weak solution of sulphuric acid and water, and exposed the plate while still wet to the electric discharge. The image developed as a broad band of irregular form, without branches or radiations of any kind.

The effect of soaking the plate in water and exposing while still wet is to reduce the radiating tendency of the spark, but not to the same extent as when sulphuric acid is added to the water. If a coin or any piece of metal with an embossed surface is placed on the plate and subjected to the electric discharge a crude representation of the design on the metal will appear on the plate when developed.

J. I. Pigg, F.R.M.S.

Fig. 6.—Electric Spark. Copper Turnings on Plate. Reversal Spot at Top of Picture.

been scattered; the iron filings give the spark a serrated edge and a thicker line; the radiations or streamers are suppressed by the presence of the iron, though they occur in the corner of the plate where the iron was not placed. When this experiment is made the iron must be carefully brushed off the plate before development, as each particle of iron that remains on the plate during development produces a black spot on the print. An interesting result is produced by placing a few paper shavings on the plate between the terminals. Fig. VI. shows the effect of the copper turnings on the electric spark. The discharge is conducted along the copper and radiates from various points. A curious effect will be noticed in this plate: at the spot where the spark struck the film reversal took place, and a black spot appears on the print. This is the

ARTHUR ALBERT COLLINS, a photographer, about forty years of age, shot himself at Dane's Inn, last week. A five-chambered revolver, with four chambers discharged, was picked up near the body. The man was removed to King's College Hospital, where he was found to have been wounded in the head, while another shot had penetrated the chest just under the heart. He now lies in a critical condition.

PINACHROME.—Dr. König, of the well-known dye manufacturers Meister, Lucius, and Brünig, who introduced orthochrom T., has discovered another cyanine, which is stated to be far superior to any other red sensitiser. It is stated in a German trade organ that the exposures for a trichromatic portrait in the studio with a cloudy sky and lens working at $f/7$ amounted to five seconds in all, whilst under similar conditions orthochrom T-plates required fifteen seconds and ethyl red plates twenty seconds.

LIGHT FILTERS FOR TRICHOCHROMATIC PHOTOGRAPHY.

Dr. E. KÖNIG gives in the current number of the "Photographische Mittheilungen" very precise directions for the preparation of dry colour filters for three-colour photography which have been specially adjusted for plates sensitised with orthochrom T.

Well-polished plate glass of about 1.2 mm. thickness should be cleaned by immersion in diluted hydrochloric acid, well washed, and then carefully polished with alcohol and ammonia. A carefully levelled slab of same size must be provided on which the plate glass when coated must be placed to set.

An 8 per cent. solution of gelatine should also be made, and after the dyes have been added the mixture should be filtered and poured on the plate glass, allowing 7 cm. to every 100 sq. cm. of surface, spreading the same with a bent glass rod if necessary.

Great stress is placed by Dr. König on the necessity of using perfectly pure dyes, such as are supplied by Meister, Lucius, and Brünig.

VIOLET FILTER.

Crystal violet	4 g.
Distilled water	100 cc.
Glacial acetic acid	5-6 drops.

Of this solution 6 cm. should be added to 100 cm. of gelatine solution.

GREEN FILTER.

Tartrazine	3 g.
Patent blue	6 g.
Distilled water	330 cm.

Dissolve by the aid of heat, and add 4.5 cm. to 100 cm. of gelatine solution.

This filter transmits the green, and dampens the yellow and blue, and absorbs orange and red, all except a narrow strip at the extreme edge of the spectrum, which Dr. König states, contrary to several authorities, to be quite innocuous. This narrow strip of red can be absorbed by the use of naphthol green, but at the expense of a prolonged exposure. Such a filter is—

Naphthol green	4 g.
Patent blue	6 g.
Tartrazine	2.5 g.
Distilled water	400 cm.

Dissolve by the aid of heat, and add 5 cm. to 100 cm. of gelatine solution.

RED FILTER.

Dianil red	5 g.
Distilled water	200 cm.

5 cm. of this should be added to 100 cm. of gelatine solution.

For making the light screens for the chromoscope for triple projection the following are used:—

BLUE VIOLET FILTER.

Crystal violet	3 g.
Methylene blue (free from zinc chloride)...	1 g.
Distilled water	100 cc.
Glacial acetic acid	5-6 drops.

Dissolve by the aid of heat; 7.8 cm. of this should be added to 100 cm. of gelatine solution.

GREEN FILTER.

Tartrazine	6 g.
Patent blue	1 g.
Distilled water	140 cm.

Dissolve by the aid of heat, and add 7.8 cm. to 100 cm. of gelatine solution.

RED FILTER.

Tartrazine	4 g.
Rose bengal	3.5 g.
Distilled water	150 cm.

and add 7.8 cm. to 100 cm. of gelatine solution.

To make the screens two similarly coloured glasses are always used, and they should be gently warmed and a few drops of purified Canada balsam (Merck, Darmstadt) should be placed on one glass, and then the other gently lowered to it, and the two should be placed on a levelled slab with one or two pieces of paper placed on top under a weight of about $\frac{1}{2}$ kilo, and left in a warm place for several days. E. J. WALL.

New Book.

"Die Photographische Kunst im Jahre 1903." Verlag von Wilhelm Knapp, Halle a/S.

Those who wish to form some idea of the tendency of photographic art in Germany, France, America, Great Britain, etc., would do well to consider the reproduction of a large number of selected photographs brought together in this work. Rather more than one hundred specimens have been reproduced, and they give a satisfactory impression of the work which attracted most attention in the past year. The composition and technique of some are excellent, but others are so crudely conceived and common-place that they are scarcely worthy of the dignity the pages of this work confer upon them. Yet as a mirror of the past, it is perhaps wise to include them. A series of papers, by persons well known in the photographic world, deals with subjects appropriate to the publication. The illustrations and typography are of the high standard to which we have so long been accustomed in the works brought out by this publisher.

ON THE CONSTITUTION OF REDUCING SUBSTANCES CAPABLE OF DEVELOPING WITHOUT THE ADDITION OF ALKALI.

THE property possessed by certain reducing substances of permitting development of the latent image without the use of alkali—simply by the presence of sulphite of soda—has only yet been noted in a small number of cases; while the relation existing between this property and the constitution of the bodies possessing it, has not up to the present, been shown in a sufficiently precise manner.

In a former study¹, published about ten years back, we had originally thought it possible to conclude that the only bodies able to develop without alkali were those containing a double developing faculty. We have since found that certain substances containing this faculty only singly may also possess that property. In the present study we propose to complete our first experiments by seeking on the one hand the substances permitting development by the sole addition of sulphite of soda, and, on the other hand, examining the conditions which furnish in this case the developing faculty.

We first tried those substances which contain only the single developing faculty. We know that this faculty depends on the presence in the same aromatic combination of two oxyhydril groups (two amidogen groups or one oxyhydril and one amidogen group substituted either in para or ortho.²

When the developing faculty contains only oxyhydrils, the reduce appears to be capable of acting only in presence of alkalies. This is the case with hydroquinone and pyrocatechin. It is not so, however, with bodies whose developing faculty contains one or two amidogen groups; for instance, paramidophenol, orthoamidophenol, para phenylene diamine, Orthophenylene diamine, Orthotolylene diamine are capable of developing the latent image when dissolved in water to which sulphite of soda has been added.

If the amidogen group or groups be substituted by alkaline residues the property appears to remain. Thus, Methylparamidophenol (metol), dimethylparaphenylene diamine can develop without the addition of alkali. On the other hand, however, the developing energy is considerably reduced if the amidogen group is replaced by an acid residue, as in glycine (oxyphenylglycine),

¹ A. and L. Lumière. Bulletin of the Société Française de Photographie, 1893.
² A. Lumière. Bulletin of the Société Française de Photographie, 1893.
Andersen. Photographische Correspondenz, 1892.

When the reducing compound contains the double developing faculty, and this faculty is formed exclusively by phenolic oxyhydrils, we find that these substances develop the latent image without alkali; but the image appears much too slowly for this method of development to be of practical use.

Such is the case with pyrogallol acid and oxhydroquinone. These substances in solution with sulphite of soda have considerably weaker developing power than compounds containing a single developing faculty, but with an amidogen group. If amidogen groups are substituted at the same time as the oxyhydrils in a reducing compound containing the double developing faculty, the developing property appears with notably greater activity than if it has only a single developing faculty. To this class of substances belong

These compounds are utilised in the chlorhydrate state, but immediately they come in contact with sulphite of soda the base is freed, with formation of chloride and bisulphite of soda. It is, therefore, the base which acts, as in the case of developers containing the single developing faculty. Their developing power is sufficient to permit of their practical use in solution in water to which alkaline sulphite is added. The increase in number of amidogen groups in the same combination seems to augment the property of developing without alkali. Thus triamidophenol (arising from the reduction of picric acid) is more energetic than diamidophenol. Its developing properties, however, cannot be utilised practically, owing to the production of oxydization which occurs during development, and which ends to a reaction inverse to that of development.

We have found that not only these substances containing the double developing faculty with amidogen groups, but also other compounds can be used practically to develop the latent image without alkali.

These are combinations of developers having an acid faculty with those of a basic function, of which metoquinone (quinomet) is a representative. We endeavoured to find what conditions fulfil the two terms of the combination in order that it may possess the property of developing without alkali. The various cases which may be presented are the following:—

- (1) Combination of a developer having a phenolic faculty with a basic or developing substance.
- (2) Combination of a developer having an amine faculty with a substance of a non-developing phenolic faculty.
- (3) Combination of a developer having a phenolic faculty with a developer of an amine faculty.

In the first class of substances, we tested the combinations of hydroquinone with different aromatic bases, particularly aniline, fluidine, quinoline, and found that none of these combinations could practically develop without alkali.

If in these combinations hydroquinone is replaced by other phenolic developers, such as pyrocatechin, pyrogallol acid, containing a single double developing faculty, the products obtained do not work in simple solution in sulphite of soda.

In the second class of substances, we examined the action of a

series of combinations between paraphenylene, diamine, and non-developing phenolic compounds such as phenol, resorcin, orcin, combinations whose preparations we have previously indicated.¹

All these substances slowly develop the latent image in the absence of alkali, but this property is incapable of practical utilisation.

Finally, all the combinations of the third class—viz., those of a developer having a phenolic faculty with another of an amine faculty—that we have assayed, act without alkali, and when sufficiently soluble in solutions of alkaline sulphite, they can be used practically.

Amongst these are all the combinations of paraphenylene, diamine, with hydroquinone (hydramine), and with pyrocatechin, but their slight solubility in solutions of alkaline sulphite prevents their practical employment. In fact, only greatly diluted solutions of very weak developing power can be prepared with these substances.

The combination of methylparamidophenol and hydroquinone (metoquinone, or quinomet), more soluble than the foregoing, enables an energetic developer to be prepared by simply dissolving in water to which alkaline sulphite has been added.

The reducing power of these developers is apparently weaker than that of substances containing the double developing faculty, such as diamidophenol. On the other hand, their developing energy may be increased by the addition of carbonate alkalies, even caustic, and this property used practically, which is not the case with developers of a constitution analogous to that of diamidophenol.

CONCLUSIONS.

The preceding study enables us to draw the following conclusions:—

- (1) In order that a substance may be able to develop the latent image without the addition of alkali, in the presence of alkaline sulphite, it needs only to contain a single developing faculty, one of the groups of which may be amidogen. This may be substituted or not, provided the substitution does not destroy the basic character of the amidogen. It is necessary also that the substance should be sufficiently soluble in alkaline sulphite.
- (2) If the substance contains only a single developing faculty, or if it contains this faculty doubly, but without the amidogen group, the property of developing without alkali is too feeble, especially in the latter case, to be practically used.
- (3) The reducing power is found to be considerably augmented in the case where there is the double developing faculty if this contains two amidogen groups. The developer may then be used practically without alkali.
- (4) The reducing power is found also to be augmented, although more feebly than in the preceding case, if the basic faculty or faculties of the developer be salified by the oxyhydrils of a phenolic compound itself possessing developing properties. The developer is then equally useful practically without the addition of alkali.
- (5) The salification of the basic faculty of a developer by the oxyhydrils of a phenolic compound possessing no developing properties, or the salification of the oxyhydrils of a developer having a phenolic faculty by an aromatic amine not containing the developing faculty, does not furnish in a single case compounds capable of developing practically without the addition of alkali.

A. AND L. LUMIERE AND A. SEYEWETZ.

MESSRS. EDMEDS AND Co., of The Photographic Works, Burchell Road, Peckham, S.E., in sending us their new price list of enlarging, printing, etc., ask us to state that they will be pleased to send any of our readers a copy on application.

THE Challenge Cameras.—Mr. J. Lizars, of Glasgow, is making the following offers in connection with his well-known Challenge Stand and Hand Cameras. A "Challenge" $\frac{1}{2}$ -plate camera, with Thornton-Pickard shutter with speed indicator, double dark slide, and three-fold tripod: the whole outfit, camera, lens, etc., for 80s., or the price of the lens only, which is of the symmetrical type, manufactured by Messrs. Ross, Limited. With each Challenge Dayspool sold until further notice there will also be presented a coupon entitling the purchaser to twenty shillings' worth of material, which may be ordered with the camera or, to ensure freshness, from time to time as may be required. Both these offers, which are fully described in the advertisement pages of last week's JOURNAL, are available for a limited period only.

¹ Bulletin of the Société Française de Photographie, 1899 (p. 31).

THE BARNET PHOTOGRAPHIC COMPETITION.

WE have decided, write Messrs. Elliott and Son, in "The Barnett Photographic Record," to hold a competition open to all users of "Barnet" products, amateur and professional, and are offering the sum of £500 in cash as prizes to the winners. The judges will be Messrs. R. Child Bayley, Thomas Bedding, Arthur C. Brookes, and A. Horsley Hinton, editors respectively of "Photography," THE BRITISH JOURNAL OF PHOTOGRAPHY, "Focus," and "The Amateur Photographer." In any case of dispute the decision of the judges will be final. Competitors may enter for any class, or for all except the Junior and Colonial Classes, which are subject to special restrictions, and any number of entries may be submitted, but each entry must be accompanied by a separate coupon, which will be found only in each packet of "Barnet" plates, papers, films, etc. The same print cannot be entered in more than one class, nor can any competitor obtain more than one prize in each class. The prints must be mounted, but not framed, and the coupon must be securely attached to the back. The prints sent in will not be returned unless this is expressly desired, and postage included with them for the purpose. Every care, we need hardly say, will be taken of the competitors' prints, but we cannot hold ourselves responsible for their safety. All the successful prints and their negatives will become our property (except in Class 9, Lantern Slides). In this one we reserve to ourselves the right of purchasing any one negative or more at the rate of 10s. 6d. each negative. The last day for receiving prints will be December 31st, 1904. Entries may be sent in any time prior to that date, but it must be distinctly understood that the competition will definitely close then, and no postponement will be made under any conditions. The results will be published in the "Record" and in the photographic press. Should the quality of work or number of prints submitted in the Classes 4, 16, and 17, Portraiture and Enlargements, be insufficient, in the opinion of the judges to warrant the awarding of the prizes, it will be left to their discretion to apportion the amount set aside to extra awards in other classes.

LIST OF PRIZES.

Class 1.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 2.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 3.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 4.—First prize, £20; second prize, £10; third prize, £5. Class 5.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 6.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 7.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 8.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 9.—First prize, £5; second prize, £3; third prize, £2; fourth prize, £1. Class 10.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 11.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 12.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 13.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 14.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 15.—First prize, £5; second prize, £3; third prize, £2; fourth prize, £1. Class 16.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 17.—First prize, £10; second prize, £5; third prize, £3; fourth prize, £1. Class 18.—First prize, £5; second prize, £3; third prize, £2. Class 19.—First prize, £10; second prize, £5; third prize, £3. There are fifteen additional prizes of half-a-guinea each in each class except No. 4. In No. 4 there are seven additional prizes each of £1.

LIST OF CLASSES.—GENERAL CLASSES.

Class 1.—Hand Camera Work: One print on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or cut films in any hand camera.

Class 2.—Landscapes or Seascapes: One print on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or cut films of any size.

Class 3.—Instantaneous Work: One print on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or cut films of any size. The subject must have some indication of motion.

Class 4.—Portraiture and Figure Studies: One print on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or cut films of any size.

Class 5.—Still Life, Fruit, Flower Studies, etc.: One print on any

of the "Barnet" papers, from a negative made on the "Barnet" orthochromatic plate of any size.

Class 6.—Architecture: One print on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or cut films of any size.

Class 7.—"Barnet" Roll Films, $3\frac{1}{2}$ by $3\frac{1}{2}$ and under: One print on any of the "Barnet" papers, from a negative made on "Barnet" roll films, size $3\frac{1}{2}$ by $3\frac{1}{2}$ and under.

Class 8.—"Barnet" Roll Films, all sizes over $3\frac{1}{2}$ by $3\frac{1}{2}$: One print on any of the "Barnet" papers, made from a negative on "Barnet" roll films, all sizes over $3\frac{1}{2}$ by $3\frac{1}{2}$.

Class 9.—Lantern Slides: For sets of six lantern slides, made on "Barnet" lantern plates, showing the best range of colours.

Class 10.—"Barnet" Bromide Papers: For sets of three prints on any grade of "Barnet" bromide paper (toned or untoned) of any size or subject, from negatives made on "Barnet" plates or films.

Class 11.—"Barnet" Self-Toning Paper: For sets of three prints, either glossy or matt, of any size or subject made on "Barnet" self-toning paper, from negatives on "Barnet" plates or films.

Class 12.—"Barnet" Gaslight Paper: For sets of three prints, either glossy or matt, of any size or subject made on "Barnet" gaslight paper, from negatives on "Barnet" plates or films.

Class 13.—"Barnet" Carbon Tissue: For sets of three prints in any colour, of any size or subject, on "Barnet" carbon tissue and transfer papers, from negatives made on "Barnet" plates or films.

Class 14.—"Barnet" P.O.P.: For sets of three prints, either glossy or matt, of any size or subject, made on "Barnet" P.O.P., from negatives on "Barnet" plates or films.

Class 15.—"Barnet" Post-Cards: For sets of three prints of any grade or subject, on "Barnet" Postcards, from negatives made on "Barnet" plates or films.

Class 16.—Bromide Enlargements.—For enlargements of any size and any subject, on "Barnet" bromide paper of any grade (toned or untoned), from a negative made on a "Barnet" plate or film.

Class 17.—Carbon Enlargements.—For enlargements of any size and any subject, on "Barnet" carbon tissue and transfer paper of any colour, the original to be made on any "Barnet" plate or film. A print from the original negative should accompany each enlargement. Enlargements must not be worked up; ordinary spotting only is allowed.

SPECIAL CLASSES.

Class 18.—Junior Photographers: Competitors must be under the age of 16. The age must be entered on the coupon. One print of any subject and any size, on any of the "Barnet" papers, from a negative made on any of the "Barnet" plates or films.

Class 19.—Colonial (British): For Colonial (British) photographers only, both amateur and professional. A set of three prints on any of the "Barnet" papers, from negatives made on any of the "Barnet" plates or films, of any subject and any size. Colonials may enter for other classes, in addition to special classes.

THE AFFILIATION PRINT COMPETITION, 1904.

THE Executive Committee are pleased to report that 285 prints, by 124 members of 28 societies, were entered for the Print Competition. The Committee regret that not more than nine societies competed for the three certificates of distinction by inducing a minimum of six of their members to enter the competition, as set forth in the prospectus. The entries of these societies reached, however, a total of 178 prints by 82 members. The decision to reduce the maximum number of prints per competitor from six to three has been amply justified. It threw upon the competitors themselves and their societies, instead of upon the judges, the duty of eliminating the less promising work, the judges being spared much unnecessary trouble and loss of time. The judges have made the following awards:—

PLAQUES.

"A Village Belle," Mrs. G. A. Barton (Birmingham Photographic Society); "Evening," G. H. Capper (Hackney Photographic Society); "The Foreman," T. Fitzgibbon Forde (Sunderland Photographic Association); "In Arcady," E. T. Holding (West London Photographic Society); "At the Smithy," Edgar G. Lee (Newcastle-on-Tyne Photographic Association); "A Wind Sea," F. J. Mortimer (Southsea Photographic Society).

CERTIFICATES OF DISTINCTION.

(1) Hackney Photographic Society; (2) West Surrey Photographic Society; (3) Sheffield Photographic Society.

Some fifty prints are being retained for exhibition at 66, Russell-square, on the recommendation of the judges, and a selection of these will be framed and circulated amongst the affiliated societies. It is impossible to state how long the prints will be wanted by the committee for purposes of circulation, but it is probable that they will be in considerable demand for some two years. It is intended to give in the printed catalogue the prices, where obtainable, at which unframed replicas can be obtained. The committee expect to be in a position to circulate the prints as from September 1st, 1904.

LIST OF PRINTS RETAINED FOR EXHIBITION AT 66, RUSSELL-SQUARE.

A selection from these prints will be framed and circulated amongst the societies.

Birmingham Photographic Society.—"Ave Maria," Mrs. G. A. Arton; "Evening," P. Bale Rider.

Cambridge and District Photographic Society.—"Norman Work—Contrast," Rev. H. R. Campion; "A Fruit Study," H. W. Chapman; "In an Elizabethan House," Rev. H. R. Campion.

Coventry Photographic Club.—"Pond Lilies," W. H. McLauchlan.

Hackney Photographic Society.—"An Autumn Day," G. H. Capper; "Across the Nave, Winchester," S. C. Stean; "Refuse Carts," Walter Life; "Ambulatory, Gloucester Cathedral," A. W. Cook; "Towing a Barge," W. A. I. Hensler; "Marguerites," William Rawlings; "The Edge of the Wood," S. C. Stean; "The Mill by the Creek," J. Westcott; "Whitby Harbour, Winter," W. Rawlings; "Coal Pit," Oliver G. Pike; "The Blind News-vendor," Frank E. Roope; "A Stormy Sunset," W. A. I. Hensler; "Alas! Alas! for the Winter Snows," W. Rawlings; "Harvesting," S. C. Stean; "Clapton Pavement," G. H. Capper.

North Middlesex Photographic Society.—"A Deserted Mill," S. E. Hall; "A Figure Study," A. G. Lawson.

Nottingham Mechanics' Institution Camera Club.—"From Darkness to Dawn," A. Marshall; "My Little Dutch," Arthur Marshall; "A Pillar of the Church," Arthur Marshall.

Plymouth Photographic Society.—"A Gleam of Light," W. Clayden.

Preston Scientific Society.—"Design for a Frieze," Miss Alice Arden; "On the Moselle," W. Phillips; "The Torrent," James Shyby.

Redhill and District Camera Club.—"Toil and Moil," T. Percival Edwick.

Sheffield Photographic Society.—"The noon of autumn's flow, When soft and purple mist, like a vap'rous amethyst, fills the overlaiden sky," Thomas U. Simonson; "The Solemn Stillness of the Wood," Thomas U. Simonson; "Wild Flowers of the Meadow," Hugh G. Person.

Southsea Photographic Society.—"In the Height of the Storm," J. Mortimer.

Sunderland Photographic Association.—"A Portrait Study," T. Higginson Forde.

West London Photographic Society.—"A River Scene," Leslie B. Holding; "Portrait Study," M. W. Cockerell; "When the Wind Blows," Bert E. Cockerell; "Fisher Boys, Dieppe," E. Walker; "Brian," T. Holding; "Recollections," E. T. Holding.

West Surrey Photographic Society.—"A Wet Day," F. G. Tryhorn; "Leaving the Jetty," W. T. Marriott; "Autumn Sunbeams," F. G. Tryhorn; "In the Old Church," F. G. Tryhorn.

MR. WILLIAM E. GRAY, F.R.P.S., of 92, Queen's Road, Bayswater, writes:—I have just received from the Lord Chamberlain a Warrant appointing me "Fine Art Photographer to his Majesty King."

THAMPTON Camera Club.—On the 7th inst., Messrs. Geo. R. and A. C. Berry gave an illustrated lecture entitled "A Photographic Tour Round the Isle of Wight." The lecture was conducted largely to the least frequented portions of the coast between Freshwater Bay and St. Catherine's Point. The Chines at Chilton, and Atherfield were described as appearing in their natural beauty, being as yet practically untouched by the hand of man. A good tribute was also paid to the beautiful lighthouse at St. Catherine's Point.

THE PHOTOGRAPHIC ASSOCIATION.

THE Official Receiver in Companies Winding-up has now issued particulars under this liquidation, from which it appears that the statement of affairs as regard creditors shows gross liabilities amounting to £7,224 13s. 5d., of which £5,274 13s. 5d. is expected to rank against the estate for dividend. The assets are returned at £1,950, but these are all claimed by the debenture holders, so that the nett assets are nil, and the deficiency £5,274 13s. 5d. As regards contributions, the total deficiency is £18,626 13s. 5d. The following is an extract from the report and observations of the Official Receiver:—

OBSERVATIONS.

The winding-up order was made on December 1st on a petition presented on November 19th, 1903, by John Done and Company, creditors for £83 17s. for goods. The Company, which was promoted by William John Le Couteur, was registered on February 16th, 1899, with a nominal capital of £25,000 in shares of £1 each. It was formed to carry into effect a provisional agreement, dated February 1st, 1899, between Le Couteur, as vendor, and T. E. Peet, as trustee, for the intended Company, which was to carry on a photographic club and deal in photographic requisites. The business was originally started by Le Couteur in February, 1896, at 14, 16, and 18, Brook-street, Hanover-square. At the time of the formation of the Company Captain Henry Connop had a considerable interest in this business, having advanced £4,500. Captain Ralph P. Cobbold had also advanced £1,250. The property to be acquired by the Company consisted of the business, goodwill, copyright in films, benefit in agencies and contracts, interest in the leasehold premises at Brook-street, and freehold and leasehold premises at Hendon, the consideration for the whole being £20,000, payable as to £5,000 in cash and £15,000 in fully-paid shares. By a subsequent agreement, dated March 29th, 1899, the agreement of February 1st was adopted by the Company with the following modifications:—The property at Hendon was excluded, and payment of the £20,000 (which was not reduced) was to be satisfied by the allotment of 20,000 fully-paid up shares. The vendor was, however, to have the right to surrender 4,750 shares, and to call upon the Company to issue to him in lieu thereof 1,250 first "debenture shares" of £1 each, and 3,500 second "debenture shares" of £1 each. No prospectus was issued by the Company in relation to the issue of the ordinary share capital. By the books, which, as stated, have been imperfectly kept, it appears that the 20,000 fully-paid shares were allotted on or about April 29, 1899, to Le Couteur and his nominees as follows:—

Connop	10,000
Cobbold	5,000
Le Couteur	4,400
William Beatty	100
J. S. Harvey	500
							20,000

According to the Company's register of members, allotments of 1,852 shares for cash have been made, making a total issue of 21,852 shares. On June 17th, 1899, the Board, in pursuance of a written notice from Le Couteur that he elected to surrender 4,750 shares in accordance with the agreement of March 29th, 1899, issued a debenture to Cobbold for £1,250 as Le Couteur's nominee. It is stated that a second debenture for £3,500 to Connop was issued at the same time, but no reference is made to it in the minutes. The register of members does not record that any of the 20,000 shares which were issued as fully paid have, in fact, been surrendered, but entries have been made in the private ledger purporting to show that £8,500 shares have been surrendered, and the statement of affairs consequently returns the number of shares outstanding as only 13,352. The debenture for £1,250 was repaid by instalments extending from February, 1900, until March 27th, 1901, out of advances obtained from Barclay and Company, bankers, and on May 1st, 1901, a debenture for £1,250 was given to them which on October 17th, 1902, they assigned to John Crow Richardson (since deceased) on his paying off their loan. On September 29th, 1902, at a directors' meeting at which Connop, E. E. Richardson, and Wilson Burgess were present, resolutions were passed for the issue of (a) £3,000 first mortgage debentures, out of the proceeds of which the existing debenture for £1,250 and interest was to be paid off and cancelled, and (b) £3,000

second debentures. Debenture bonds for £1,250 were given to Richardson apparently in exchange for the debenture which he had acquired from Barclay and Co., which, however, he did not surrender. On July 31st, 1903, Mr. Edwin Hayes, of 28, Basinghall-street was appointed Receiver of the Company's business and property by the Court, on behalf of the debenture holders, and on November 23rd, 1903, an order was made for him to sell the whole of the Company's assets, exclusive of book debts, for a sum of £450. The sale has been carried out, and the purchaser is in possession. The only balance-sheet issued was as at January 31st, 1902. An approximate balance-sheet which was subsequently prepared, as at June, 1903, but was never issued, showed that there had been a total loss of £2,966 1s. 8d. since the formation of the Company.

Exhibitions.

BRECHIN PHOTOGRAPHIC EXHIBITION.

On Saturday the Brechin Photographic Association opened an exhibition in the Corona Hall, Brechin. The walls are draped with canvas, surmounted by a frieze, which displays at intervals names of photographic historical interest, amongst these we noticed that of Traill Taylor, the predecessor of the present occupant of the B.J. editorial chair. The wall is divided into panels by strips of wood stained green, and each class is indicated by an artistic plaque modelled by Mr. David Waterston, A.R.E., Brechin, who has been the guiding spirit in the scheme of decoration.

The committee, with Messrs. J. Kirk and Wm. Lamont, exhibition secretaries, and Mr. J. C. Robertson, convener of the hanging committee, have spared no work to make their exhibition a success, and the complimentary criticisms bestowed on it at the opening ceremony must have gone far to alleviate the fatigue of their labours.

The judges were Messrs. J. Craig Annan, Glasgow; Wm. Crooke, Edinburgh, and David Waterston, A.R.E., Brechin. The awards are all of one value, viz., bronze plaques specially designed by Mr. Waterston. These were left to the discretion of the judges, and it is evident that the quality of the exhibition met their approval as they awarded in all twenty-one plaques. Four gentlemen were awarded two each, to wit, James Patrick, Edinburgh; Arthur Marshall, Nottingham; J. C. Robertson, and J. Kirk, Brechin.

At the opening ceremony Mr. R. W. Duke, vice-president, presided, and introduced Mr. Wm. Shaw Adamson, president, who briefly declared the exhibition open. There was a large attendance of the notables of the district.

The exhibition will remain open for a week, and a complete series of evening entertainments has been arranged.

The entries forward number 432, including invitation exhibits from Mr. J. Craig Annan, Glasgow; Mr. Wm. Crooke, Edinburgh; Mr. Alex. Keighley, Keighley; and four prints, the work of D. O. Hill, kindly lent by Mr. J. Craig Annan. Mr. Waterston has also sent a representative exhibit of his etchings and mezzotints.

Trade exhibits are displayed by Kodak Ltd., London; W. Watson and Sons, London; A. H. Baird, Edinburgh; Geo. Houghton and Sons, London; Wm. Middlemiss, Bradford; Elliott and Sons, Barnet; Wellington and Ward, Elstree; Burroughs, Wellcome, and Co., London; John J. Griffin and Sons, London; J. Lizars, Glasgow; W. Lamont, Norman Anderson, Steele, and A. C. Milne, Brechin.

The exhibition as a whole contains much good work, and the committee have been successful in securing exhibits from many leading workers on both sides of the Border. The judges have evidently considered the open portraiture and open lantern slides classes the strongest (the portraiture received most support it having 101 entries); as to each of these classes they have awarded four plaques, but the open landscape is undoubtedly a strong class, and includes, over and above the two pictures awarded plaques, splendid work, much of it previously medalled. The Federation Associates' class filled well and was a worthy exhibit, which is satisfactory considering that it was the first of its kind held in the country.

The members are to be congratulated on the work exhibited in the members' class that much of it was quite fit to rank in open competition is shown by the fact that Mr. J. C. Robertson took two plaques in the other sections.

The full list of awards is as follows:—

Class I.—Landscape, Seascape, and River Scenery (Open).—"Shepherd's Care" (218), James Patrick, Edinburgh; "The Birch Tree" (264), E. W. Prevost, Ross, Herefordshire.

Class II.—Portraiture, Genre, and Figure Studies (Open).—"The Evening of Life" (73), James Patrick, Edinburgh; "In Pensive Mood" (77), John Spark, Perth; "My Little Dutch" (79), Arthur Marshall, Nottingham; "Head of Old Lady" (85), John Terras Markinc.

Class III.—Animal Studies (Open).—"Springtime" (280), J. C. Robertson, Brechin.

Class IV.—Any subject, not included in preceding classes (open).—"The Chapel. Haddon" (172), Arthur Marshall, Nottingham; "Begonias" (190), D. W. Kyle, Edinburgh.

Class V.—Lantern Slides, Sets of Four (Open).—(384), Godfrey Bingley, Leeds; (389), F. G. Tryhorn, London; (390), Geo. Booth, Preston; (405), Lake Falconer, junr., Blairgowrie.

Class VI.—Confined to Associates of the Scottish Photographic Federation.—"Spring Sunshine" (113), J. C. Robertson, Brechin; "The Clouds Lay Cradled Near the Setting Sun" (116), A. W. Hill, Lochboisdale.

Class VII.—Landscape, Seascape, and River Scenery (Members).—"Closing Hours" (341), R. C. Dalgity.

Class VIII.—Portraiture, Genre and Figure Studies (Members).—"Practising" (358), J. D. Ross; "Declining Fires" (366), J. Kirk; "Modesty" (373), James Silver.

Class IX.—Any subject not included in Classes VII. and VIII. (members).—No award.

Class X.—Lantern Slides, Sets of Three (Members). (409), J. Kirk.

Class XI.—Best collective exhibit from any society included in the Scottish Photographic Federation. (Rule—secretaries of societies may enter any number of pictures, not less than five from Classes I, II, III, IV, and VI, but this must not include more than two pictures from one exhibitor. In awarding this prize the judges will be requested to take into consideration the strength of the competing societies). Blairgowrie and District Photographic Association.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

The fifteenth annual exhibition of the Society was opened to the public on the evening of Saturday, the 5th inst., when Sir Henry Trueman Wood, M.A., delivered the opening address. It will remain open until Saturday evening the 12th inst., when the Mayor of Camberwell will present the prizes to the successful competitors. The exhibition is held as on previous occasions at the Public Bath, Camberwell Green, S.E.

We were glad to find that a successful effort had been made to give the hall an aspect more in accord with an exhibition of work of art, and less the appearance of a fair, than it has presented on former occasions. The huge structure which constituted the stage for the lantern has been abolished, very much to the advantage of the scene, and except for the disturbing influence of the phonograph with its characteristic timbre, reminiscent of the steam-organ of the roundabout, and the primitive decorative efforts of some of the stall holders, the arrangements were as well calculated to make the show attractive as the architecture of a public swimming bath would allow. It certainly adds to the comfort of visitors, particularly those who are more interested in the pictures than the lantern exhibition, and whose only opportunity of viewing them is in the evening, to hold the lantern show in a separate hall, thus avoiding turning down the lights in the exhibition itself. A word of praise is due to those responsible for the hanging and arrangement of the pictures. A new covering had been provided for the screens, of appropriate tint and a neat moulding in place of coloured drapery, with the result that the pictures themselves were better displayed. Greater care than usual seemed to have been taken in arranging the pictures on the screens, and, altogether, the Society appears to have recognised that to keep the place it has won for its exhibition, it must best itself.

In portraiture, etc., the work of the members does not seem to improve as it should. Most of it is of the casual kind that has characterised this and other Society exhibitions in the past, and few of the exhibitors have attempted the constructive in the treatment of their subjects. The picture by Harold Moore, which

ceived the first award, although a pleasing portrait, hardly rises beyond the level of the average studio work of a good professional photographer, and is on the accepted orthodox lines. The head of a girl, by G. J. T. Walford, which the judges also distinguished, is better in its intention, but fails to be quite satisfactory, first, from the technical defect that the higher tones of the carbon print have washed up, leaving patches of white where delicate gradation is essential to harmony, and secondly, from the ill-chosen position of the figure in the picture. Better in many ways is the figure of the market woman, by the same author, but here a good subject is spoiled by the palpably artificial surroundings. In architecture a great deal of the work is commendable. A. Bedding's "Undercroft, Wells," is admirable, and in suggesting that the composition and balance of the picture would have been improved by the light from the windows stretching further across the picture, we are not suggesting that the photographer has failed in anything that came within his control. As it is, the picture will satisfy even keen critics of this class of work. C. H. Oakden's "Cathedral Interior," which receives the second award, is a commendable work. In striving after a subdued effect, however, the author has produced a degradation of tones which may be described as muddiness. Among many works which deserve praise are "The Open Door, St. Maclou," by F. W. Gregg; "The Eastern Crypt, Canterbury," by E. R. Bull, and "Llanthony Church," by J. T. French.

The landscape class contains not many works of distinction, but we made a mark against "Autumn," by W. H. Rogers; "Night's Prelude and Rolling Mists," by G. J. T. Walford; "A Sunny Day," by E. R. Bull; "Weary They Wend Their Way," by E. W. Taylor; "The Close of Day," by W. F. Slater; "By the Roadside," by W. E. Nicholls; "Across the Dens," by T. Moyser; "The Birchwoods," by E. P. Rogers; and "Bare are the Trees and Lingerin Lights," by W. Page.

It was with disappointment we viewed the small class for pictures, by members, which have been medalled during the year. "The Mowers," by E. W. Taylor is a sorry representative of the Society's triumphs.

The lantern slides, both in the members' and open classes, constitutes one of the strongest points of the exhibition in comparison with current work in photography. The entries are numerous, and a large proportion of the slides are of a very high standard of excellence. The Edwards Memorial Competition, instituted in memory of the late F. W. Edwards, President of the Society, for the best reproduction of a picture in colours, resulted in an easy victory for A. Bedding. It is an interesting competition, and it shows what differences of opinion there must be with regard to the tone value of colours. The judge of this competition was Mr. E. J. Wall. Another competition, which we think is a new feature in an exhibition, is one instituted for the best collective exhibit from a technical school. There were two entries, the Goldsmith's Institute and the Woolwich Polytechnic. In neither case do we think that the organisations concerned are to be complimented upon their efforts to demonstrate the results of the teaching. In both exhibits there are photographs which prudence would have withheld from public view, although we must also say these are examples of special applications of photography which are not without merit.

The open classes are fairly representative of the current work of the day, although the clashing of several exhibitions of importance has probably robbed the exhibition of some of the best photography that is going the rounds.

The judges were Messrs. H. W. Bennett, J. C. S. Mummery, and B. Wellington. In most of the awards the prize takes the form of a plaque in silver and bronze, specially designed. An illustration of the design appears in the catalogue. It appears to represent a male, scantily clothed, suffering unutterable agonies from some reason not apparent. Artistically, we hope it is not to be taken as standard of art knowledge of photographers generally.

THE AWARDS.

MEMBERS' CLASSES.—Portraiture: Silver plaque, Harold Moore; bronze plaque, G. J. T. Walford.

Architecture: Silver plaque, A. Bedding; bronze plaque, C. H. Oakden.

Landscape: Silver plaque, G. J. T. Walford; bronze plaque, W. Page.

Excursion Pictures: Bronze plaque, E. W. Taylor.
Lantern Slides: Silver plaque, E. R. Bull; bronze plaque, W. E. Nicholls.

Pictures Medalled between February 16th, 1903, and February 15th, 1904: Gold medal, E. W. Taylor.

OPEN CLASSES.—Portraiture: Silver plaque, Arthur Marshall; bronze plaque, F. W. Hicks; bronze plaque, F. J. Mortimer.

Architecture: Silver plaque, W. A. Clark; bronze plaque, P. W. Crane.

Landscape: Silver plaque, F. J. Mortimer; bronze plaque, C. E. Wanless; bronze plaque, D. M. Filshill.

Lantern Slides: Silver plaque, A. Bedding.

Stereoscopic Slides: Silver plaque, F. G. Tryhorn; bronze plaque, H. Wormleighton.

BEST PICTURE IN THE EXHIBITION.—Gold medal, F. J. Mortimer.

BEST COLLECTIVE EXHIBIT, TECHNICAL SCHOOLS.—Bronze plaque, Woolwich Polytechnic.

NOVELTY CLASS.—Bronze plaque, withheld.

BEST STALL.—Silver plaque, J. Lizars, Glasgow and London.

EDWARDS' MEMORIAL COMPETITION.—Bronze medal, A. Bedding.

FORTHCOMING EXHIBITIONS.

March 15-17.—Brentford Photographic Society.

March 15-19.—Arts and Crafts Exhibition (Shrewsbury).

March 22 to April 5.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

March 25 to April 9.—Northern Photographic Exhibition. Hon. Exhibition Secretary, Chas. F. Inston, F.R.P.S., 25, South John Street, Liverpool.

April 6-13.—Croydon Camera Club. Hon. Exhibition Secretary, C. U. King, Hurst Bank, Selsdon Road, Sanderstead.

May 11-18.—Plymouth Photographic Society. Hon. Secretary, Wilfred Grist, 105, Old Town Street, Plymouth.

May 24-28.—Devonport Camera Club. Hon. Secretary, A. J. Catford, 78, Charlotte Street, Devonport.

THE ROTOX COMPETITIONS.

The following is a list of the prize winners in these competitions, for which over 3,000 prints were submitted. The judges were Messrs. Thomas Bedding, F.R.P.S. (Editor of *THE BRITISH JOURNAL OF PHOTOGRAPHY*); A. Horsley Hinton (Editor of "The Amateur Photographer"), and H. Snowden Ward (Editor of "The Photogram").

Class I. (Size 2½ by 3½).—Grade I.—First prize: Mr. Fred Fry. Second prize: Mr. Henry Hodge. Extra prizes: Mr. S. T. Vernon, Mr. Arthur Wood, Mr. Charles J. Desbottes, Mr. J. F. Gunn, Mr. H. Kerr.

Class I. (Size 3½ by 2½).—Grade III.—First prize: Mr. W. Gundry. Second prize: Mr. T. Harold Reade. Extra prizes: Mr. James A. Hall, Mr. Edgar James Richmond, Mr. P. R. Smith, Miss Ethel Ramonde, Mr. D. Steeves.

Class II. (Size 4-plate).—Grade II.—First prize: Mr. Edgar R. Bull. Second prize: Mr. M. P. Durn. Third prize: Mr. James Coster. Miss Ettie Collier, Mr. William Findlay, Mr. A. W. M. Dickins, Mr. H. Warren Hutchinson, Mr. James H. Saunders, Mr. James M. Browning, Mr. W. S. Fothergill, Mr. Edwin J. Philips, Mr. J. R. Batey, Mr. A. W. Cooper.

Class II. (4-plate).—Grade III.—First prize: Mr. A. W. Cooper. Second prize: Mr. L. Havenhand. Third prize: Mr. A. M. Walters. Miss Alice Armstrong, Mr. Robert Telfer, Mr. Samuel Swinden, Miss Ettie Collier, Mr. Edwin Carratt, Mr. Herbert Mills, Mr. Alfred Cracknall, Miss Sybil Aird, Mr. S. Elwin Neame, Mr. W. E. Walker. Special prize (10s. 6d.): Mr. Arthur Ashe.

Class II. (4-plate).—Grade VI.—First prize: Mr. Harry W. Witcombe. Second prize: Mr. J. Peat Millar. Third prize: Mr. D. G. Urquhart, Mr. D. M. Seven, Mr. A. W. Cooper, Miss Sybil Aird, Mr. W. James Coster, Mr. William Baker, Mr. W. Parkinson Curtis, Mr. W. Scott Elliott, Junr., Mr. H. Burley Mess, Mr. Paul Williams, Miss Isabel Purdon.

Class III. (Size 5 by 4).—Grade I.—First, second and third prizes. No prizes awarded. Mr. Harry J. Horton, Miss Ettie Collier, Mr. Walter Wilson, Mrs. Turnbull, Mr. John W. Pharez.

Class III. (Size 5 by 4).—Grade III.—First prize: Mr. James Shaw. Second prize: Mr. James Dunlop. Third prize: Mr. William Baldwin, Mr. W. G. Hill, Mr. John Vandle, Mr. Fred Judge, Mr. L. Havenhand, Mr. A. H. Almond.

Class III. (Size 5 by 4).—Grade V.—First prize: Mr. Herbert Bairstow. Second prize: Mr. Charles J. Reade. Third prize: Miss Sybil Aird, Mrs. J. Turnbull, Mr. Frank W. Gregg, Mr. Albert E. Burchett, Mr. Sam Swinden, Mr. G. A. Fowkes.

Class IV. (½ plate size).—Grade II.—First prize: Mr. Arthur Smith. Second prize: Mrs. K. R. Image. Third prize: Mr. V. C. Baird, Mr. Walter C. Gurney, Mr. A. W. Cooper, Mr. Robert Low, Mr. W. H. Mack, Mr. R. S. Park, Mr. Sam Swinden, Mr. Fred Blenkinsopp, Mr. F. W. Harrop, Mr. Fred Hartley, Mr. L. Havenhand.

Class IV. (½ plate size).—Grade III.—First prize: Mr. Stuart Elwin Neame. Second prize: Mr. Alfred Grumwood. Third prize: Mr. Robert Low. Extra £1 ls.: Mr. Arthur Smith, Mr. Herbert C. Hughes, Mr. John Smith, Mr. John J. Hartley, Miss Adys Curran, Miss Mordaunt, Mr. James V. Banks, Mrs. G. Barton, Mr. Herbert Smith, Mr. Leonard E. Hopkin, Mr. Herbert Bairstow. Extra 10s. 6d.: Mr. A. W. Cooper. Second extra 10s. 6d.: Mr. Thomas E. Evans. Third extra 10s. 6d.: Mr. V. C. Baird.

Class IV. (½ plate size).—Grade VI.—First prize: Mr. J. Peat Millar. Second prize: Mr. T. W. Lambert. Third prize: Miss Sybil Aird, Mr. Stuart Elwin Neame, Mr. Dan Dunlop, Mr. James H. Saunders, Mr. Handal H. Rutter, Mr. James Ingham, Mr. Herbert C. Hughes, Mr. H. E. Doughly, Mr. Clarence Penting, Miss Kate Smith, Mr. Albert Haynes.

Class V* (Whole plate).—Grade II.—No awards.

Class V. (Whole plate).—Grade IV.—First prize: Mrs. P. A. Barton Hartopp. Second prize: Mr. H. Nouvelle Rudge. Third prize: Mr. Frank Wilkey, Mr. Charles J. Read, Mr. W. Foster Brigham, Mr. Victor Stouffis, Mr. John Archer, Mr. H. W. Strong.

Class V. (Whole plate).—Grade V.—First prize: Mr. Victor Stouffis. Second prize: Mr. James Shaw. Third prize: Mr. Herbert Bairstow, Miss Agnes Tomlinson, Mr. T. Moysey, Mr. William Baldwin, Mr. Fred W. Lovatt, Miss H. R. Image.

New Apparatus, &c.

The Barnet (yellow sensitive) Orthochromatic Plates. Manufactured and sold by Elliott and Sons, Ltd., Barnet, Herts.

It is with much satisfaction that we learn Messrs. Elliott and Sons have added to their list a series of orthochromatic plates. The introduction of the first orthochromatic plates is still vividly impressed upon our memory, and likewise how, after a short period of interest in the question, photographers neglected it for a number of years. But at the present time there appears to be a genuine desire on the part of our best photographers to give a more truthful monochromatic rendering of colour, and we feel sure that Messrs. Elliott and Sons' endeavours to satisfy their friends in this respect will meet with due recognition. The principal characteristic of the new plate is improved sensitiveness to the yellow or visual region of the spectrum. In this respect the ordinary plate is very weak, and photography on that account has been very severely criticised by artists. Our trials of the plate were made with a rather deep yellow screen, and we found not only great relative sensitiveness for yellow, but that orange, bright and deep red also were given in fairly correct gradation. Blue, on the other hand, was considerably subdued, deep ultramarine being rendered about equal to deep red, and green brighter than either. It will thus be seen that there is a fairly correct representation of the leading colours. Such being the case, the plate, when used with a suitable screen, should give a very satisfactory rendering of colour values. We find the plate is of fair rapidity, and what is perhaps of greater importance, that there is a full range of gradation, with ample density in the high lights. It is a pleasure also to observe that the characteristic of the Barnet emulsion asserts itself in this orthochromatic series. We refer to the complete absence of any trace of fog and the fineness of the grain. We submitted the plate to a severe test by shortening the exposure and forcing the development, but it bravely resisted the attack and yielded a very satisfactory negative.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
11.....	Watford Photographic Union	<i>Negative Making.</i> Mr. Chapman Jones.

CAMERA CLUB.

THE lectures at the Camera Club of late have had but a very remote connection with the camera, except that they have been illustrated by means of that indispensable aid to the platform speaker. But beyond this their photographic interest has been almost nil, and we have therefore abstained from detailed notice or criticism. As a matter of record of the club's proceedings, we may note briefly what has taken place since our last notice appeared in these columns. On Monday, the 22nd ult., Professor Henry Louis gave an interesting account of the world's most northerly railway, which is a line which crosses Scandinavia, having a total length of 200 miles, a large portion of which is within the Arctic circle. The main purpose of the line was to open up the huge iron deposits of Norway and Sweden. The lecture was well illustrated with photographs of the wild scenery through which the railway passes, and of the up-to-date loading machinery employed for dealing with the ore when it reaches the port of departure. On the following Thursday Mr. Percy Wright and Mr. E. H. Carpenter described "One Square Mile of Holland," the particular mile referred to being comprised in the village of Volendam, which is situated on the Zuyder Zee. This is a village which has been for years well known to a few artists, and other visitors find it hard to get accommodation there, for the inhabitants do not lay themselves out for the entertainment of strangers, and unless the visitor brings with him some kind of introduction from one who has been there and knows the people, he has not much chance of finding his wants provided for. In this case, a friendly letter from the late lamented Phil May to the proprietor of the establishment where he himself had found a lodging was the open sesame to the village, and thereafter the two friends found themselves made welcome everywhere. They made good use of their time, and in little more than a week took a couple of hundred photographs, which illustrated Volendam and its simple and quaintly garbed people in a very thorough and picturesque manner. Some

persons would have found little to photograph in what they would probably describe as a flat and uninteresting country, but the lecturer, Mr. Wright, and his friend were happily of a different opinion, and were able to make a number of photographic notes full of meaning and information.

A well-known artist, in the person of Mr. Percy Macquoid, lectured on Thursday, the 29th, on the "Evolution of Form in English Silver Plate." He dealt with domestic plate from Tudor times forwards, and showed a number of most excellent photographs of beautiful examples of silver-ware which are treasured in some of the colleges of Oxford and Cambridge, and in the hands of the City Companies. "The Great Dominion," a lecture on Canada, was given by Mr. Edgar Wallace on the 3rd instant.

In the subject of Mr. Maunder's recent lecture, Mr. J. H. Knight writes to the Club Journal:—"Alluding to difficulty in photographing the planets owing to rotation, the following occurred to me. If the photographic films which show faint traces of the image superimposed, a far better result is obtained than by viewing one only. I do not know how long an exposure might be made on films without showing traces of movement, but I presume at least ten minutes to half-an-hour. I would suggest taking several photographs of the planet on successive evenings, and at the same Martian hour, and superimposing these. By this means a total exposure might be made equal to several hours. The long exposure would permit of the use of coloured screens. It would probably be useless to try this in our latitude, but if tried in a favourable locality I have it would very likely throw light on some of the doubtful questions. Possibly the so-called canals than run N. and S. would be photographed, owing to rotation, but those running E. and W. might possibly be detected.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

APRIL 4TH.—Mr. R. P. Drage in the chair. The Convention slides, presented to the Association by Mr. Welford, were shown. Samples of dried bromide prints by various methods were shown, and the difficulty in obtaining uniformity of result pointed out; the prints in black and white were all of an even depth, but when toned the differences were very marked, showing that the ultimate colour of dried bromide cannot be controlled, as it is entirely dependent on the exposure, and amount of silver deposited by the developer. Hon. Recorder read a short description of Dallmeyer's "Adon" and exhibited a camera fitted with a stigmatic lens f. 5.3, a telephoto lens and an Adon, and the Adon alone, all at the same extension which enabled the members to judge of the capabilities of the instrument, together with a number of specimens of work done with the Adon, comprising portraits, and landscape, and architecture.

THE ADON.

It is a curious fact, but a fact it is, that a telephoto lens has been used by a large number of photographers as a fearsome instrument, that does not at all come into the category of ordinary lenses, it requires an extraordinary amount of skill in its use, and that its capabilities are principally limited to taking photographs of Mont St. I wish this evening to disabuse the minds of any who may be present of these ideas, and to show them that a telephotographic instrument in no way differs from an ordinary lens in its application and use.

To put the case very briefly, a telephoto lens is a lens of an exceedingly great focal length in relation to the camera extension which is used. The little lens about which I am speaking—Dallmeyer's Adon—is probably the smallest and simplest telephoto lens that has ever been made, and its applications are so numerous that they are pointed out, I fancy few photographers will care to doubt one. In appearance, and in less degree in construction, it resembles the simple telephoto lens which was first invented by Dallmeyer in 1891; but it has one important characteristic which distinguishes it not only from that lens, but from all other telephoto lenses, that while a complete optical instrument in itself, it is designed to be used in front of an ordinary lens, and that when used under these circumstances it can be used at the "infinity focus" of the original lens, and a mark made on the tube, so that after once setting this operation need not be repeated when distant objects are to be dealt with. The Adon consists of two lenses, the

front one being a single achromatic lens of very large aperture, and as well corrected as possible for spherical aberration, the back lens being an achromatic negative lens of smaller diameter, and having a negative focal length half that of the positive lens. These are mounted in an aluminium tube, in which, by means of a rack and pinion, and also a loose lengthening piece, there is a considerable range of extension allowing the lens to be separated, so that it may be used with a camera extension of two or three inches, or approached so closely that even the point at which parallel rays are transmitted is past, so that an infinite length of bellows could be used. The mount is fitted with an Iris diaphragm, and this is graduated with a series of marks, each of which represents an aperture half the area of the preceding one. When these marks are read in conjunction with a table which is issued in the Adon booklet exposures can be readily calculated by the ordinary methods of view meter, actinograph, or exposure table, whether the camera extension in use be four or forty inches. Although, in the first place, the Adon was designed as its name implies, to be added on or used in front of an ordinary lens, it is equally well adapted to be used alone, and this becomes a very handy tool to the landscape photographer, as the specimens show, while at the same time it is to be by no means despised for portraiture.

To come to its practical applications, we will suppose that one has a hand camera with an ordinary rapid rectilinear lens, or better still, one of the rapid anastigmats. All that has to be done is to set the lens to its "infinity focus," and after having screwed the Adon on the front in the manner shown on this model, to focus the image on the screen by means of the rack and pinion. It is quite practicable to engrave a scale on the tube of the Adon, so that objects at varying focal lengths will be brought into sharp focus without altering the camera extension. When used in this way it will be found that although the Adon produces an image at about twice the scale of the rectilinear with little reduction of intensity that the whole of the plate is not covered. This may to a certain extent be remedied by racking out the camera an inch or so more, and lessening the separation of the components of the Adon. The result at these two extensions is shown in these two prints. When it is possible to remove the lens from the camera altogether the Adon takes a wider view of things. At a camera extension of 5 in. it will be found that there is a magnification of nearly three diameters while a quarter-plate is covered to the corners. With an extension of 8 in. a half-plate is covered, and so on, a 15 x 12 being quite within practical limits. In order to secure a greater range of separation the black tube immediately behind the front lens is removable, so that when used alone for extensions of over 10 in., or when used in front of an ordinary lens, the positive and negative lenses may be brought nearer to each other. The specimens which I am now showing will serve to illustrate the wide range of subjects to which the Adon is applicable. The portraits shown received from 14 to 30 seconds' exposure, while the views had hardly more than a second or two, except when a yellow screen was used in conjunction with a slow plate, when about 30 seconds was the limit.

PHOTOGRAPHIC CLUB.

FEBRUARY 24TH.—Mr. Barton Kent, F.R.G.S., took a large meeting of members and friends, by means of lantern slides from his own negatives, a tour through "Southern Spain." Starting at Gibraltar, and passing through Algeiras, he went to Granada, showing many magnificent slides, detailing some of the beauties of the Alhambra and the surrounding scenery, finishing with the wonderful Cathedral and scenery of Seville. Everywhere can be seen traces of the Moorish conquerors. On the 2nd inst. Mr. Wm. Gamble, on behalf of Messrs. Penrose and Co., gave a history and demonstration of the "Sinop" process. This is a simplified colotype process, the improvement being that the plates can be prepared and supplied in the insensitive condition commercially. In that state they will keep good for any length of time. After sensitising in a 2 per cent. bath of bichromate, they are dried in an ordinary room. Exposure varies from two to ten minutes to daylight, and after well washing and soaking in a glycerine bath they can be printed from in an ordinary letter-copying press. As many as 6,000 copies have been taken from one plate, and it was still in good condition.

DEVONPORT CAMERA CLUB.

At the last meeting Mr. W. H. Mayne delivered a lecture on the ozotype process. Ozotype he described as a modification of the carbon process, and produces permanent pictures in various monochromes of high artistic quality. Its advantage is there is a distinctly visible print-out image upon its surface which is to form the support of the picture. The initial print and subsequent picture are correctly rendered in regard to right and left; therefore, no transfer is required, no safe edge is necessary. No blisters are formed, however hot the developing water. The simplification of the process has now reached such a point that amateurs have no difficulty in producing a perfectly sharp and beautiful picture within an hour after printing. Nearly all the former pitfalls and chances of error have been removed, and ozotype may now be regarded as one of the simplest photographic printing methods. Specimen prints by the Ozotype Company and the lecturer were shown.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION,
LIVERPOOL BRANCH.

A MEETING of the Liverpool branch of the Professional Photographers' Association was held on Friday, February 26th, at headquarters, Dale Street. Present: G. Watmough Webster, president, in chair; A. Priestly; O. Looser; E. Vanderbilt; R. Waite; A. F. Mowl; W. Warrington, hon. secretary. The hon. secretary read letters from secretary, parent association, and it was arranged that one of the members should call on a prospective member. The question of granting certificates of proficiency to assistants, arising from the action of the parent association in the matter, gave rise to an interesting and animated discussion. Most of the members had had unpleasant experiences through engaging incompetent assistants, and been put to inconvenience and loss. It was generally felt that something could be done, and members were asked to bring their ideas on the subject to next meeting, with a view to devising a plan for ridding the profession of people who, as one member put it, "ought to be breaking stones," which would be greatly to the benefit of photographers, and of bona-fide assistants.

CROYDON CAMERA CLUB.

MARCH 2ND.—At a special meeting convened for this date, Mr. S. H. Wratten was unanimously, and with much enthusiasm, elected president of the club in place of Mr. Hector Maclean (resigned). Mr. Wratten, in returning thanks, alluded in most appreciative terms to his predecessor, and the energy he had displayed on the club's behalf, an expression of feeling which was subsequently emphasised by a cordial vote of thanks being accorded Mr. Maclean without a dissentient note. Mr. Lionel Kough then showed the Nernst lamp in operation, which he regarded as highly satisfactory for enlarging, possessing, as it did, a comparatively small illuminating area, coupled with a highly actinic light. On the previous Wednesday a lecture on Morocco, illustrated by nearly 200 capital slides, was given by Mr. John H. Avery, who holds the somewhat unique position of photographic instructor to the Sultan. In a chatty and humorous manner Mr. Avery narrated his experiences, and graphically described his somewhat onerous journey from Larasche to Fez, and life in the capital, palace, and provinces. Mulay Abdul Aziz, to give the Sultan his full name, Mr. Avery said, was not only a powerful monarch, with absolute sway over the country he ruled, but, judged by Western ideas, a gentleman in every sense of the term. He had also shown great firmness and moral courage in dealing with disorder, and not the least interesting part of the lecture, described a large expedition led by the Sultan to subjugate hostile tribes, in which expedition Mr. Avery was the only European. It was also interesting to know that the Sultan did not believe in "You press the button, and we do the rest" system, and was soon an adept in carbon, platinotype, and bromide, as well as a first-rate operator. The studio formed a miniature palace, and included dark and enlarging rooms. It was taken out in pieces, and erected by a small army of workmen, under the direction of Mr. Avery. A vote of thanks was tendered the lecturer, and deservedly; but perhaps the best compliment of all was furnished by the state of the club rooms, which were crowded to their utmost capacity.

CATFORD AND FOREST HILL PHOTOGRAPHIC SOCIETY.

On a recent open evening Mr. W. R. Frederick Avery delivered a lecture on Java, Borneo, and Siam to the members and friends of this Society. Mr. Avery, who was introduced by Mr. H. J. Pearce, has but recently returned from a stay of nearly five years in South Borneo, and his lecture was brimful of exciting incidents. About 100 excellent photographic lantern slides, taken by Mr. Avery, many of them in country never before explored by a white man, and under the greatest difficulty, were shown. The lecturer's humorous, racy, and wholly extempore delivery was highly appreciated by the large audience. His reference to the mineral wealth, and his explanation of his construction of miniature man-of-war out of old tins, etc., the battles to keep the water from flooding the diamond mines, and his criticism of the Dutch administration were listened to with the keenest interest. During the evening some mineral specimens and a Dyak sword were handed round for examination. Mr. Avery explained that he was writing a book of his experiences in Borneo, and we would suggest his illustrating it with some of the excellent photographs that were shown to the Society. He also promised to present a copy to the Society's library as a souvenir of his visit; it should prove a valuable and most interesting work. Dr. Arnold spoke as to a visit he made to Java some years ago, and in proposing a vote of thanks to Mr. Avery fully endorsed his remarks as to the possibilities of the countries, not only from a mineral, but also from a photographic point of view.

Patent News.

The following applications for patents were made between February 22nd and February 27th, 1904:—

- Colour Photography.—No. 4,668. "Improved process for producing photographs in colours." Alfred Cleaver and Henry Marcusson.
- Print Cutters.—No. 4,679. "Improvements in or relating to photographic print cutters." Leonard Helliwell.
- Printing Frames.—No. 4,686. "Improvements in or applicable to photographic printing frames." Otto Sichel.
- Cameras.—No. 4,831. "Improvements in photographic cameras." Robert Ballantine and Matthew Ballantine.
- Dark Rooms.—No. 4,872. "Improvements in and relating to dark rooms for photographic purposes." Complete specification. Ernest Molt.

News and Notes.

THE "Homœopathic World" states that Professor William Harvey King, of New York, and Mr. Hammer found that if a tube containing radium is immersed in water for a time, the water becomes radioactive and is capable of affecting a photographic plate. Professor King said to be testing the therapeutic value of water that has thus been subjected to the action of radium.

THE City's Art Collection.—A goodly number of people, including possibly many of our readers, do not seem to be aware that the Corporation of the City of London possess a very fine collection of pictures by the best masters, and that it is open daily free to the public. The already fine collection is being continually added to, and has just received an addition by gift of some more valuable pictures, which are now on view. One of these is "An October Morning," by the late Mr. W. Osborne, which has been presented to the Corporation by the community of artists as a memorial of the esteem and regard in which the late artist was held by them. Another addition is "The Slave Market at Cairo," by W. J. Müller, also a presentation. It may be mentioned that the Corporation has loaned three of its notable pictures to the St. Louis Exhibition, and they are now on their way. Some may imagine that Art receives no attention in the City, and that business is the only thought there, but let them pay a visit to the Guildhall Art Gallery, or the Royal Exchange, and see the fine fresco

dy there by our leading modern artists, and that idea will at be dispelled. From time to time the Corporation have loan itions at which pictures from private collections are shown that are be seen by the public at other times, but the permanent collection be seen at any time and free of charge, for the City does not stoop ate money," nor does it expect one to buy a catalogue.

WHEN I announced a week or two ago that Mr. J. W. Zaehnsdorf lecture at the Piscatorial Society on "Colour Photography," and assed that the audience would have a treat that evening, I I was on safe ground, and the event proved that I was. Mr. dsdorf gave a simple and easily understood explanation of the iples involved, the use of the three-colour filters for the making e three negatives, the printing and mounting of the positives, he other operations involved in the preparation of the finished e, and what was more or less of a mystery to many became an book by the aid of the excellent way in which this somewhat use matter was treated by the lecturer. The illustrations—n slides projected on the Society's screen—were beautiful indeed. flowers, landscapes, interiors, and subjects of every sort, all ng with the colours of Nature—colours produced, moreover, by graphic methods, and not by the hand of man—provided an e treat that few who were present will readily forget. It was ghtful exhibition, and when I say that the slides were pro- by Mr. Zaehnsdorf's famous lantern, and that under the manage- of Mr. Ernest Zachnsdorf, I have, I am sure, said enough to my readers that in the showing of the slides "perfection could ther go." That the heartiest thanks of the audience were to the Messrs. Zaehnsdorf, *père et fils*, goes without saying, any of us also gave an inward vote of thanks to that splendid for the extremely able manner in which it had done its duty ister to our pleasure and instruction.—"Dragnet," in "The y Gazette."

UGHTON'S MONTHLY.—Published by Messrs. George Houghton n, Ltd., of 88 and 89, High Holborn, W.C., the purpose of w journalistic venture is stated in a foreword to be as follows: e never yet was a journal published that did not have some- o say about its aims and intentions in the first number, and in e have no desire to be singular. "Houghton's Monthly" is come of a desire to aid and assist our customers in every e way. Instead of, as formerly, sending out new articles with catalogue description, we shall endeavour to give actual, al working instructions and details that can but be of the t possible assistance to the photographic dealer and the s of his staff. Until a piece of apparatus, appliance, or line ographic material has become well known—and even the most articles were unknown once—the dealer is bound to be ded with questions about it. If he has only a bare trade ion to rely upon, he is awkwardly placed, and customers, or e we had better say possible customers, will go away dis- ; whereas, if the enquirer finds that his questions are d immediately, he is interested and becomes a purchaser. not going to supply a verbose and prosy description of our s, but just terse, intelligent, and, above all, practical infor- that will be at once easy to assimilate and interesting to t. At different seasons we shall describe the most saleable and lines, and all our dealer friends may rest assured that we e everything in our power to improve their trade. All our customers will receive a copy of "Houghton's Monthly" on ng day; and we shall be pleased to mail a copy every month photographic dealer's salesman if he will make application and tell us the name of the firm by whom he is employed. re the co-operation of the photographic trade for our mutual and we are quite convinced that we shall succeed in interest- We are the largest wholesale photographic dealers in the Kingdom, if not in the world, and we can supply our cus- with a variety of apparatus and material that is absolutely d. Our regular customers already know this; but perhaps y be a few readers of this issue who are not aware of the facilities we can offer, and we invite them to send for our l, and compare our trade discounts with those of the firm dealing with at present. That's all we ask. We have no to what the result will be. We know!

Correspondence.

- * * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.
- * * * We do not undertake responsibility for the opinions expressed by our correspondents.

PROFESSIONAL GRIEVANCES.

To the Editors.

Gentlemen,—The grievances of the average photographer are great. First one and then another branch of his legitimate trade is being snatched away and exploited by unscrupulous firms. Following the extract of beef maker's happy notion is a firm doing enlargements for the public at a price that the photographer has to pay for them. They are systematically canvassing all England and doing an immense amount of harm. It seems a pity that there are no means of stopping this cut-throat business.—I am, yours faithfully,

F. B. PEARSON.

76, Church Street, Stoke Newington,
London, March 4th, 1904.

[It is a pity that our correspondent and many more similar complainers do not strengthen their own and their confrères' hands in resisting unfair competition by joining the Professional Photographers Association, whose third annual dinner is being celebrated this very evening.—Eds. B.J.P.]

INTERNAL REFLECTION IN CAMERAS.

To the Editors.

Gentlemen,—In your issue of to-day's date I note that Mr. C. Welborne Piper suggests the use of orange paper as a lining for cameras. Unfortunately, however, he has overlooked the fact that bromide paper with which his tests were made is of inferior rapidity to plates, and also that while orange light has absolutely no effect on the former it does slightly affect very rapid plates, and still more so those that are orthochromatic. Orange paper is, however, an admirable material for lining cameras which are intended for use with slow non-chromatic plates. It has the special virtues of a non-reflecting surface, and a satisfactory absorption of all but the orange rays of the spectrum.

I cannot agree with Mr. Welborne Piper that a circular hood over the lens is not so efficacious in cutting off superfluous rays of light as a square one. As a matter of fact the advantage lies, if anything, with the former. A short cylindrical metal tube well blacked inside, and fitting on the front of the lens can hardly be improved on for getting rid of the surplus light caused by employing a lens intended to cover a larger plate than the one in use. It is far more convenient to fit than a square one, and can be made without difficulty to take the ordinary cap or shutter of the lens.—I am, gentlemen, yours very truly,

A. LOCKETT.

88, Brook Street, Kennington, S.E.,
March 4th, 1904.

THE METRIC AND DECIMAL SYSTEMS.

To the Editors.

Gentlemen,—It is evident from Mr. Gotz's letter that he is not well enough acquainted with English methods of measurement and calculation to be a competent judge of the relative merits of the English and metric systems. It is somewhat rash to praise one system as the best when you don't clearly understand the others. The duodecimal system of working feet and inches (in feet, primes, seconds, thirds, etc.) is not a new one, as Mr. Gotz seems to think, but a very old one, fairly well known to every English schoolboy, and very familiar to a large number of practical men who use it constantly. This not being the place to give lessons in elementary arithmetic I must refer Mr. Gotz to the arithmetic book for fuller information, and if he gets hold of a good book he will also find the equally general algebraical equations used to facilitate multiplication, without which equations a pure decimalist cannot get on any better than the most vulgar fractionist. If he goes into the matter carefully he will probably find that the "accepted rule" of the text book is no better adapted to its purpose than is the "accepted rule" for multiplying $6\frac{1}{2}$ by $4\frac{3}{4}$, or that for doing long division. If he goes

into the matter carefully he may discover that cross multiplication meets the case best, and, further, that that rule is equally suitable for yards and feet, and also for mixed fractions in many cases, though seldom of any use at all with decimal quantities. If next he cares to measure up say, all the brickwork in his own house, first in feet and inches, and then in metric measures, and finally squares and cubes the one lot of dimensions by duodecimals and the other by decimals he will find that the first method requires fewer figures and less time; most of the duodecimal "squares" requiring no working figures at all, while very few of the decimal measurements can be worked without. Such an experience as this will probably prove to him that the much despised English measures have certain advantages when you know how to make use of them.

With regard to the working of fractions it is hardly necessary to point out that a man who cannot multiply simple mixed fractions like $6\frac{1}{2}$ by $4\frac{1}{2}$ "in his head" is not worth a salary in many modern business offices where much more difficult problems have to be dealt with mentally in the shortest possible time. Working out on paper is an operation not to be thought of nowadays, excepting in special cases, and (this was just the point I tried to make in my former letter) many sums expressed in decimals cannot be quickly solved mentally without turning the decimals into fractions. This applies to pretty well all decimals that represent simple fractions, and it applies with considerable force to decimals representing 1-3, 1-6, 1-7, and 1-9. Some of the sums given in my letter on page 198 are alarming in decimals, but turn them into fractions and the answers are apparent without the use of a single working figure in any case. Frequently decimals and vulgar fractions have to be used together, either alternately or mixed, and when reciprocals occur decimals are an abomination.

Decimals are invaluable, but if we use them alone we cannot reach a high state of efficiency, hence any monetary or metrical system that acknowledges decimals only is essentially defective.

A good example of the inefficiency of decimals is afforded by calculations relating to insurance premiums. If you keep to English money and bar decimals excepting only when they are most convenient, it will be difficult to suggest any rate of insurance that the expert cannot solve within a minute without the use of working figures. Possibly five per cent. of the rates will require working out, but only a few of the five per cent. will require more than a dozen figures. Try the same thing with decimals alone, and only a few sums at rates accommodating themselves to decimals can be worked mentally, and the majority will require figuring. A very ardent decimalist made himself extremely ridiculous not long ago by publishing a series of sums of different types worked in duplicate by decimals and by ordinary English methods. He proved his contention that decimals saved time by working every English sum incorrectly, and capped all by declaring that space would not admit the working of a particularly easy sum that an insurance clerk could have solved in a minute with hardly any figures at all. It is a pity that nearly every decimal advocate should suffer from the same want of practical knowledge of arithmetic.

"Duodecimal" in his very interesting article states that "we must learn to think in tenths below a half or quarter," but this is just what we cannot afford to do. By thinking in thirds, sixths, eighths, sixteenths, sevenths, etc., we can get through the work in much less time, and this is all important to the man whose income varies directly with the speed at which he calculates. The slow laborious methods of the German clerk who can think only in tenths are of no use when speed is essential.

It is somewhat difficult to understand all Mr. Gotz said in his paper with regard to the metric system, and in some parts the only thing clear is the fact that he is wrong. First, the litre is not equal to 1000cc., and, second, the litre of water used for making solutions does not weigh 1000gms., but the very awkward quantity of 997.8066grms.; hence with the metric system you cannot very well measure the water for a solution that is to be used by weight, though you can adopt this generally most convenient course with English measures. The metric system as sketched by Mr. Gotz is very pretty on paper, but we can hardly say that in practice it really exists. The occasional tangle that one gets into over a litre that weighs 997.8066grms. and equals 1000.16cc. beats any sort of complication that exists with the English systems. The metric system is very useful on certain occasions, but on others there are better systems available.

Here is a metrical problem for Mr. Gotz. I should much like to know how a confirmed metrical enthusiast solves it.

Appliances for weighing large quantities of liquid, not being available, how would he make up at a normal temperature of 62° F. about two litres of an exactly accurate ten per cent. by weight solution, which is to be used in small weighed metric quantities. The accuracy is to be real, not approximate, and the salt used may be assumed to be anhydrous and perfectly soluble at 62° deg. F.

I note that Mr. Gotz considers our present crown to be worth 96 halfpennies, at which rate of exchange I shall be very pleased to take all the silver crowns he can lay hands upon.—Yours, etc.,
March 5th, 1904. C. WELBORNE PIPER.

ON SOME ADVICE TENDERED TO PROFESSIONAL PHOTOGRAPHERS.

To the Editors.

Gentlemen,—The professional photographer ought to consider himself a fortunate person, as he is always receiving good advice, or rather what his self-constituted instructors think good advice, from people who appear to know much better how to conduct his business than he does himself.

But I am afraid he is not so grateful as he should be. He is constantly accused of being conservative and unprogressive, and probably he is. But his well-meaning critics and monitors seem to forget some important matters. They forget that the professional is often compelled to stick to well-known processes, because his customers will have them, and will not take to new things for a long time; and in fact, they think the new process has become fashionable, and is the proper thing; although in their hearts they prefer the old one.

They do not want artistic photographs, they want them what they call "clear." They say they do not want to see themselves through the kind of mist. So, after all, the photographer is compelled to produce the "usual thing," because his customers want it. One man built up a very large and successful business by, as he expressed, supplying what people wanted, and not what he thought they ought to want. This is one reason for being conservative. Another is that his assistants are accustomed, and his plant is arranged, to carry out certain processes, and he cannot change all these directly a new process is introduced. He must wait to see if this new thing has come to stay, and whether it is going to pay, if it does stay. After the success of a new process is assured he has to train his staff for the new method and alter his work-rooms as well; and all these things means expense and waste, and probably delay.

There is no doubt the professional has his faults (he would not be human if he had none), and among them may be noted his remissness in allowing the local chemist to capture the dealer's trade, and also apathy in the matter of combination for mutual protection. But this last-mentioned matter, thanks to the exertions of yourself, Editor, and some prominent photographers, things are improving slowly, and we may hope surely. And some day we may hope to have photographers strong enough and united enough to put a stop to undervalued treatment by trusts and such like.

These thoughts have been suggested by the advice tendered in last week's BRITISH JOURNAL on the subject of artificial light, etc., and speedy finishing of orders. Much of that advice is excellent, and I speak from experience, for, for some years, I have never done daylight printing if I could avoid it. I get so heartily sick of the length of time it takes to complete an order that wherever possible I do bromide printing. But it took years of pushing to get customers to have it, and now the only silver prints I ever do are for publication, and the London agents will not take anything else.

The advice referred to however, shows almost complete ignorance of the business of the professional. We are told we should have studio lighted by some artificial means so that photographs can be taken in any weather, at any time, but sitters will not come in if the weather is bad, and as soon as the plate is exposed, the operator has to take it to the developer, the developer to the retoucher, the retoucher to the printer, the printer in an hour passes the prints to the mounter, the order is completed and sent away within twenty-four hours. How lovely all this sounds; should not we like to do business like this? much, oh no! But alas the professional knows all this is but a beautiful dream.

Those of us who have tried artificial light know something of the expense, and if we used it always would not there be a nice little bit

end of each quarter? Then we also know that it is much more difficult to use, and very few assistants can use it well. Some one may say that there was a successful photographer in London who used nothing else. "True, O King!" and he produced the best portraiture ever seen; but, in the words of Hans Breitmann, "Where is doty now?" I believe many photographers would say, that now that they have some years' experience of artificial light, that if they had not the expense and trouble it entails, and the small amount of work it produces, they would never have tried it.

All this eloquent description of a clockwork-like business does not take into account the fact that sitters do not come with this beautiful regularity, but that one day (at rare intervals), they almost tumble over another in their haste to be photographed, but the next day not perhaps, appears. What then becomes of the operator, the developer, the printer, the retoucher, and the mounter, if the first day's work is all done? Are they to sit down and wait for the next day? Then just think of the methylated spirit that would be used in drying the negatives and prints, and it does not improve either one or the other. Of course we get the water out of the spirit by using a pump, but do not let the Excise find it out or there will be ructions; we use potassium carbonate, or, still better, an old lime from the kiln, but it is very unsatisfactory, and the spirit does not do its work properly.

At a most important point has been omitted, and that is, where the proof come in? Oh! if we could only go on straight with the work how happy we should be. Every professional knows the trouble of proofs. It is seldom less than a week, and often longer, sometimes months, before we hear anything about it; and then something has to be altered and a fresh proof sent, and then another interval of waiting. Perhaps, prints of all the negatives must be seen, and, after perhaps, a re-sitting, because the dress does not fit, and so on, and so on, *ad nauseam*. Some one will suggest sending proofs from the sitters, but I tried it once, but never again. Every sitter, without exception, demanded a fresh sitting. Many people receive the prints and take no notice until a bill is sent, then they want to sit

and do not quite see how this beautiful business-like arrangement, as it is called, is going to work. I am afraid there is too much human nature in the sitters for that. It seems to me, too, the customers get harder and harder every day.

But I am quite convinced that most professionals would do well to try the quicker methods of printing to a greater extent. When the weather is good daylight printing goes quickly, and the average man can get on very well, and he does not feel the need for the other methods, but when Christmas is at hand he finds he cannot get the work done, and he has perforce to try bromide. But his assistants are apt to get at it, and perhaps his negatives are not quite suitable, the prints are not good, and his customers will not have them. It is not the fault of the process. Bromide paper of one brand or another is capable of producing good prints from almost any kind of negative. There is only one negative so bad that it will not give a passable print in the end. And what an advantage that is, for we all, "even the best, are not infallible," and we all get poor negatives at times.

They give a few instances of the advantage of quick printing. Only one week a gentleman, leaving England in a few days, sat on Wednesday and saw the proofs on Thursday, and received his prints on Friday morning. A year or so ago I had to copy and supply five hundred prints of a sketch, within a week, and they had to be brown.

They were all done and mounted on invitation cards, within a week. An expert on seeing one of the prints pronounced it a good carbon. This disposes of another difficulty, that of colour. Some people object to the cold black of ordinary bromide prints; there is no reason why they should be black. The numerous toning methods published give an extraordinary range of browns and sepias. Of course it would be dishonest to sell such prints as carbons.

As a whole, then, if photographers are not as wise as they should be, they are not quite such fools as some people imagine.—I am, etc.,

B. H.

18th, 1904.

A veteran wood-engraver, Mr. James Davis Cooper, died on Friday, February 27th, at the age of eighty-one. He was educated at the City of London School, and thence passed into the studio of Mr. Cooper, where he speedily developed the remarkable talent which

made him one of the most successful wood-engravers of the last period of the art, before photographic processes succeeded in extinguishing it. One of the earliest works by which he made his name (says "The Times") was the edition of Mrs. Barbauld's "Hymns in Prose," 1863; but this was only one of many, and Cooper took a large share in that development of book-illustration which made "the sixties" memorable in the history of British art. Later he worked with Randolph Caldecott in the well-known illustrations for the Macmillan edition of Washington Irving's "Old Christmas" and "Bracebridge Hall." He also engraved the illustrations for the works of many famous Victorian authors, beginning with the Queen herself. His hand is to be seen in many of the books of Darwin, Huxley, Owen, Livingstone, and a large number of others. For some years before his death Mr. Cooper had ceased to engrave.

In the course of the debate in the House of Lords last week on the Metric Weights and Measures Bill, Lord Kelvin gave an amusing illustration of the confusion arising from the use of different systems of weights, says "Nature," for in some experiments with a rifle he had put in a charge which might have caused a disastrous accident if the mistake had not been found out in time. The Marquess of Lansdowne also gave an instance of the confusion arising from the use of different weights in this country and on the Continent. A friend of his travelling abroad sent an English prescription to a local practitioner and received a box of pills of the size of small marbles, which, however, he did not take. The chemist came and said that his assistant did not know the difference between a grain and a drachm, and had put 30 grains of calomel into each pill. The illustrations given by Lord Kelvin and the Marquess of Lansdowne of the misadventures that may arise from the simultaneous use of two different systems of weights and measures show the advisability of there being only one international system.

Some years ago the late Grant Allen wrote a series of entomological papers for the "Strand Magazine," which were beautifully illustrated by Mr. Frederick Enoch, who has consented to visit us a second time and give a lecture upon the subject. The fact that he has recently been taking photographs of living insects by means of the Sanger Shepherd three-colour process will make this evening specially attractive.—A very ingenious and interesting method has been devised by Signor Carlo Baese for producing photo-reliefs. He employs the ordinary swelled gelatine method, the novelty of his invention consisting first in the method of lighting, and secondly in the method of producing the required negative. The results are very good, and are stated to be produced with ease and certainty.—A subject which is of great interest and has always had a certain halo of mystery surrounding it—the effects of lightning, and protection therefrom—will be brought before the members of the club by Mr. Alfred Hands, F.R.Met.S., during the month, when we may expect from his authority some extremely interesting data and information which will doubtless encourage useful discussion, and it is hoped that among the audience some will have apposite experiences to relate.—After Easter a small one-man show of some of the work of Mr. Tom Reveley, of Wantage, will, we hope, appear on our club walls. Mr. Reveley is a professional photographer who is not only an excellent portraitist, but has a speciality in the photography of pedigree animals. Surrounded as he is in the counties adjoining his residence by many training quarters and breeders and exhibitors of Shire horses, high-class cattle and dogs, the work at which he is continually occupied will, no doubt, be of considerable interest to many of our members who breed or exhibit.—"Camera Club Journal."

Answers to Correspondents.

- **All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- **Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- **Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*
- **For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- J. A. Horsburgh, 4, West Maitland Street, Edinburgh. *Photograph of the late Rev. W. W. Smith.*
- A. Hubbard, 7A, Exchange Walk, Nottingham. *Photograph of the Rev. J. Given.*
- F. Whaley, Weston Villa, Cheltenham. *Photograph of Four Dogs of the King and Queen.*
- H. Leake, Arcade Studio, Kirkgate, Wakefield. *Photograph of the Wakefield Trinity Football Team.*

W. J. BENNETTS.—The address is Manchester.

REGISTRATION OF DESIGN.—"CONSTANT READER" writes: "Would you kindly inform us if there is any way of effecting registration design of a portrait frame, preventing others from manufacturing the same design?" In reply: "The design can be registered at the Patent Office, and it will then become your property. If you write to the office, Southampton Buildings, W.C., enclosing a stamp, you can obtain the necessary forms which will give every information."

DEFECTIVE NEGATIVES.—"SPOTTED NEGATIVE" says: "The two negatives enclosed were treated in the usual way: Fresh developer, pyro-soda, Ilford's formulæ. We developed quarter, half, and whole plates. Cadott's and Ilford's special and Monarch all with same result—spotted. Kindly say the reason of it. It never happened before?" In reply: "The cause of the defects is obvious. The plates were not dusted before they were put in the slides."

RESIDUES.—PADDY says: "I am thinking of saving my hypo fixing baths (plates) for residues; will you, please, say (1) What strength to use liver of sulphur? (2) What quantity in each gallon of hypo bath? (3) How long does it take to deposit, and how is one to tell when it is so? (4) Is there an objectionable smell arising from the operation?" In reply: (1) The strength of the solution is immaterial; (2) Add the solution so long as it produces turbidity, then stir up well; (3) A day or two; (4) Yes; a very objectionable smell.

TONING—COLOURING.—KISMET asks: "(1) Will you kindly inform me what causes the red brick tones in toning prints and how to avoid same? (2) I should also be glad if you will tell me what are the pigments used for working up bromides and platino-types?" In reply: (1) You do not say the kind of paper you employ, but whatever it may be the red tones are probably due to the toning bath being deficient in gold, or the prints are left too short a time in it. (2) Ordinary water colours mixed to the tint of the pictures.

SPOTTY PRINT.—"SPOTS" says: "I am herewith sending you a print on matt C.C. paper, and shall feel obliged by your giving me your opinion as to the cause of the white spots. These appear in about a week or ten days! They are toned with sulphocyanide, and are worked with a glossy C.C. paper, which I have used successfully for years, and with unvarying success. I cannot understand the cause, and shall be pleased if you can explain it?" In reply: "The spots appear to be due to minute particles of some injurious matter, as dust, settling on the prints whilst they are in a moist state—probably while they are drying. Spots are

frequently caused in that way. The print has been returned desired.

ASCERTAINING COPYRIGHT.—A. LEWIS says: "Having recently obtained possession of an old photograph, which does not bear any marks or name by which it can be identified, I would esteem it a great favour if you will answer the following questions: (1) Where can I find out if a photo has been copyrighted? (2) Where do you copyright a photo? (3) What do you copyright the negative or the print?" In reply: (1) Only by searching the register at Stationers' Hall. If you do not know the name of the one who took it, or the title of the picture, it will be somewhat difficult task. (2) At Stationers' Hall, Ludgate Hill, E.C. If you send us two prints and one shilling and sevenpence we will effect the registration for you. (3) The picture which includes the negative.

BORAX AND BORACIC ACIDS.—"A. C." writes: "Can you give me any information as to borax, boric acid, and boracic acid, its chemical use in photography; also, could you refer me to any medical work indicating the difference of use in the above three named so far as medical treatment is concerned? Then, again, there is a powder and a crystal also described as borax or boracic acid, are these the same substance under two names?" In reply: Borax and boracic acid are two different things. Boracic acid and boric acid are one and the same. Borax is sometimes used with gold as a toning agent, called the "borax bath." We may refer you to one or other of the medical journals for the uses of these substances in medicine. It is a query in no way connected with photography.

LANTERN SLIDES.—"PROFESSIONAL" asks: "Will you kindly tell me what is the cause of slides melting when in the lantern? I have made some hundreds of slides, both in business and for my brother, who lectures a great deal. I am also what you might call a professional lanternist, and never, until using a straw lantern here, have I spoilt a slide before, and I have shown to some of the best lecturers of the day. My brother has just finished a lecturing tour, and all went well until at Croydon where the lanternist spoilt some twenty slides for him? (1) Is it caused by defective plates, or by a badly ventilated lantern? (2) Would varnishing protect the film and be more likely to prevent the slides melting?" In reply: (1) The melting was brought about by the films containing moisture when the slides were bound up. If there were no moisture there would be no melting. (2) There would be no harm in varnishing the slides though it is not necessary if they are made thoroughly dry before they are bound up.

STUDIO QUERIES.—W. J. MARTYN says: "I have just taken over a studio which I find will want repainting, rearranging, etc. Would you be good enough to give me the following information?—(1) What colour do you advise for painting studio? (2) Studio is well lit; east and west. Side windows from floor to ceiling, and north top-light; all unobstructed. At present it is all clear glass. Do you recommend the whole of the glass to be whitened, or frosted over, and what is the best mixture to do this with, on the inside? (3) Of course, one of the side windows will have to be blocked up, or curtained off. What is the best opaque material to get for the purpose? (4) I purpose using two sets of thin curtains, running on wires, to diffuse the light when necessary. What colours do you advise? I wish to get a good soft diffused light; would you advise enough curtains to cover the whole of the lights?" In reply: (1) Any light, unobstructed colour that will accord with the surroundings. A pale green or French grey, for example. (2) The roof may be obscured, in the summer months, by stippling it over with flour paste mixed with whiting; or light, sliding wooden frames, covered with tracing-linen may be used. (3) A very good cheap material for the purpose is the thick blue stuff used for butchers' smocks. One set may be thin muslin and the other the material just named; that is, if you have two sets. It will be well to have two means of covering all the lights.

THE Rotary Photographic Company, Ltd., state that a new roll of celluloid film of their manufacture will appear on the market almost immediately. The name of the new film is "Roto."

EX CATHEDRA.

Coming Exhibition. We may remind our readers, many of whom may wish to show specimens of their work, that, as a sequel to the exhibition of engravings and etchings held last summer at the Victoria and Albert Museum, there is to be this year a display of pictures produced by mechanical means, photogravure, half-tone, etc. The colour section should be especially interesting, for we seem to know just now how we stand in the matter of chromatic printing. There have long been rumours of efficient power machines, which will turn out vast quantities of such prints, and we are all looking forward to the possibility of a journal with coloured pictures. The attempts already made in this direction have not been very successful. It is not difficult to turn out a few such pictures; it is when a long run is attempted that the work comes very "ordinary." We venture to suggest that exhibitors of such products should be invited to send in books containing several hundred "pulls" of the same nature, so that it can be judged whether the bulk is as good as a sample. The exhibition is to be held under the auspices of the Education Department and the Society of Arts, and Sir William Abney is Chairman of the Committee appointed to advise the Board. Any of our readers who may wish for further information concerning it should apply to the Secretary, Exhibition of Mechanical Engravings, at the Board of Education, South Kensington, S.W.

Fraudulent Photographs. At the present time there is no question that a glaring fraud on the public is being committed by many unscrupulous photographers for a little additional profit. We allude to the palming off of silver prints of the Velox type, or "platinomatt," as platinotypes. In most price-lists special prices are quoted for platinotypes, usually double, or more, than those charged for silver prints, and silver prints of the kind just referred to supplied in their place. This is a fraud that a stop should be put to in the interest of honest photographers and the public alike. Those unscrupulous photographers who are committing this fraud, systematically, may possibly not be aware that they bring themselves within the Merchandise Marks Act, and are incurring heavy penalties. Also that any of their customers so defrauded can proceed against them for the fraud. We are sorry to say that this system is not entirely confined to the cheaper class of photographers. Silver prints of the Velox type, if of good quality, are not easily distinguished from veritable platinotypes, and we have seen many that we would not, in the witness-box, swear were not without applying a chemical test. There is now more than one firm making platinotype papers. Could they not combine and prosecute those who are supplying silver prints for platinotypes? They would, by taking action, alike be protecting their own interests and those of the public. Platinotypes are undoubtedly permanent; silver prints are not, and if they fade, discredit is brought on the former process, as those who have paid for platinum pictures imagine they have got them, notwithstanding their fading. Not so very long ago the British Bacon Curers' Association prosecuted a number of cheesemongers for selling, as English, American and Canadian hams, and they were mulcted in very substantial penalties and costs. It seems a pity that the makers of platinotype papers do not institute similar proceedings against those unscrupulous photographers who are supplying silver pictures as platinotypes.

* * *

Three-Colour Photography.

The interest being taken by experimentalists in tri-chromatic photography is undoubtedly on the increase. Scarcely a week passes but we have something new to chronicle on the subject. Last week a new sensitiser for the red rays was announced, for which greater sensitiveness is claimed than is possessed by the recently-introduced "Orthochrom T." It has been named "Pinachrom," and has been brought out by the firm of Meister Lucius and Bruning, of Höchst a/M. If this new sensitiser for the red fulfils the claims made for it, it is an acquisition, for hitherto the exposure for the reds have been unduly long to get presentable results. It would seem that greater interest

is being taken on the Continent in tri-chromatic photography than in this country, for all recent advances seem to come to us from abroad. Three-colour photography should specially interest professional portraitists now that coloured photographs are once more coming to the fore; but, so far as we are aware, they are taking little or no note of it, at least in England. It must, however, be confessed that up to the present better effects can be obtained by hand-colouring, by a skilled painter, than by the three-colour method; but will that always be so? Many years ago—thirty or forty—Ducos du Hauron proposed the use of the carbon process for the production of the three-coloured pictures, and fairly good results have been obtained with it. One of the difficulties with it, however, is that the tissue, when wetted, expands, the paper as well as the gelatinous coating, and contracts again when it dries, but not to its original dimensions. Hence with pictures, except of small size, there is a difficulty in securing accurate registration when the three images are superimposed, the one on the other. A patent has been taken out in this country, and also in Germany, for a carbon tissue that should obviate this difficulty. Instead of the pigmented gelatine being spread on paper, it is coated on a very thin film of celluloid, which has previously received a coating of indiarubber. The image is printed through the film of celluloid, and then developed upon it, and afterwards transferred to paper, which the rubber substratum permits of easily being done. As the celluloid film is quite unaffected by water, there is no expansion in the image as there is when the gelatine is coated on a paper support. A carbon tissue of this character should be of great service in tri-chromatic photography, as it would obviate some of the troubles now met with. This tissue, we are given to understand, is already on the market in Germany, but, so far as we are aware, it has not yet been introduced commercially in this country.

* * *

Photographers' Assistants. At the last meeting of the Liverpool Branch of the Professional Photographers' Association the question of the granting of certificates of proficiency to assistants, originated by the parent Association, came under consideration. This is an important matter with professional photographers, and many know to their cost the inconvenience they have been put to through engaging incompetent operators, etc. If one turns to the advertisement columns of the JOURNAL for the past few weeks and compare the numbers of "Situations Wanted" with the "Situations Vacant," he will see that the supply greatly exceeds the demand—that is, so far as quantity is concerned; but does it apply to quality? We sometimes hear high-class photographers complain of the difficulty they have in getting really good operators—gentlemen who have ability in posing and lighting the sitters, and are gentlemanly in manners—even when very liberal salaries are paid. At the present time, when plates are bought ready for exposure in the camera, and paper ready for the printing-frame, there is very little to be learnt before presentable results—indeed, technically good ones—can be produced; but all that does not constitute a first-class photographer, who can take charge of a good-class studio. Here a man of some culture, and with artistic ability and considerable tact is required, and such men are not so easily met with. At the present time the majority of "office boys" possess a camera of some sort, who, with dry plates and P.O.P.s, after a time consider themselves proficient photographers, and in glowing colours advertise themselves as such at wages really below those that unskilled labourers of the "navy" type are allowed by their Trades Union to accept, considering the hours they will have to work. Again, employers frequently

advertise for first-class operators and retouchers, sometimes to take management of a branch, and offer a salary for which it is ridiculous to expect a really competent man to accept, and, as a result, he sometimes finds that he has engaged a man of the type just referred to. Could he expect much other? A great deal of the photographic work nowadays is done by apprentices, male and female. The apprentice is either taken with a premium, or at nominal wage, or both, for a term, by people who are themselves quite incompetent to really teach the apprentice his or her trade, their object being really to get their work done for nothing, or for a quite nominal wage. What is the outlook for such apprentices? Whether the professional Photographers' Association will be able to remedy this state of things remains to be seen. We believe that in Germany people, including photographers, are now obliged to undergo some sort of examination as to competency before they are allowed to take apprentices. This on the face of it, seems of some protection to the apprentice. If such a law were in force here, we opine there would be fewer apprentices to photography than there are at present.

* * *

Free Portraits.

It is a matter of intense wonderment that this swindle which has been exposed and torn to rags and tatters in our own columns, in those of our photographic contemporaries, and, it may be said, by the entire Press, provincial and Metropolitan, should still continue to flourish. As to Tanqueray, he seems to thrive upon the free advertisement given him by universal denunciation, as well as he does upon the remittances of his dupes, and while he keeps out of difficulties with our police by residence in France, he has many imitators in this country, who, encouraged by his success, follow as closely in his footsteps as they dare to go. But the marvellous part of the business is that people will not be warned, and we must either believe that they like being swindled, or that they never read a newspaper. It is a terrible thing to think that we have among us quite a large section of the human family which is so sluggish of intellect, and generally dull and inactive, that it takes little heed of what goes on around its uneventful boundaries. It is this type of person who has never heard of Tanqueray. The same uninteresting person has also never heard of the confidence trick; he is a staunch opponent of vaccination, and he always seeks a gas escape with a lighted match. In the latter case it may be said that he fulfils his destiny in going in "where angels fear to tread." This person is a constant source of danger to the community, and the question will some day be raised in Parliament as to a possible extension of the use of the lethal chamber in his favour. But until the public becomes educated up to viewing the subject of idiotic irresponsibility in this sensible manner, we must do our best to protect those who are likely to fall an easy prey to the sharper and the free-portrait monger. We do not suppose that this JOURNAL is read by anyone who is likely to be attacked by Tanqueraymania, and therefore it is almost waste of precious space to advise the victims of that malady, to let those who have infected them with it, and ask to be paid for doing so, seek their remedy in court of law. County-court judges have had so many cases of the kind before them that they are beginning to understand all about the methods adopted by those who undertake to make portraits and enlargements free of cost. A batch of cases came up the other day before the sheriff at the Aberdeen Small Debt Court, when the plaintiff, who traded, of course, as a "company," had some pertinent questions to answer, which were put to him by his Honour. "Were the enlargements done for nothing in order that a frame might be sold? Did the plaintiff go in for this kind of business through amiability?" and

forth. We were glad to see that the plaintiff was non-suit in every case, but not on the score of swindling, as we should have hoped, but for quite another reason. It seems that the canvasser for these "free" portraits had, in every case, transacted his business with the wives of those who were ultimately sued for payment. One witness said that she told the canvasser to call and see her husband with regard to the matter, but she was informed that they preferred not to deal with men. He might possibly have given expression to the thought, which was probably in his mind, that men sometimes have hard tips to their boots; but however this may be, the predilection for female custom led to the discomfiture of the plaintiff. It was held that as a photograph was not a necessary, the husband was not liable for what his wife had ordered. For the present, therefore, there is a slump in free portraits up North, but, for the reasons already adduced, we fear it will not be for long.

the Chromo- scope.

We can procure most things nowadays through the medium of the penny-in-the-slot system—chocolate, butterscotch, cigar lights, postage stamps, postcards, etc., by the minor machines, and on the Thames Embankment there is a more imposing arrangement by which refreshments of various kinds are procurable by coin-freed apparatus. But we were not aware that a feast of colour was attainable by such means until the other day we saw in one of the London railway stations a contrivance which held out this hope. The word "chromo-scope" was familiar enough in connection with Mr. Ives's autiful apparatus, the most perfect ever devised for showing photographs both in relief and colour. This word was subsequently shortened to Kromskop; but even under its Americanised title the apparatus did not attract the attention of the British public as it was reasonably expected to do, and it is unfortunately seldom seen now. Was the railway-station chromoscope identical with Ives's instrument? Had the latter fallen so low as to be placed on the same footing as chocolates and peppermint drops? Such were the questions which occurred to us as we approached the new apparatus. But our doubts upon the point were quickly settled, for we saw that the new thing did only one lens, and, of course, the Kromskop must have two in order to give the stereoscopic relief. Perhaps after all it was only a *réchauffé* of the antiquated chromo-scope, which used to delight and distress the eyes of folk at lantern shows, and were regarded as quite an indispensable part of the entertainment. No, it could hardly be this, for when we came to read the label on the machine we found that the promised reward for the slotted penny was the view of "a series of beautifully-coloured designs in liquid formation" (observe the neat way in which the mention of those who are not teetotallers is attracted by the use of the word "liquid"). These designs, which, we were told, "baffle description," are thrown on a screen by an electric light, and we are also told that the entertainment is "amusing, instructive, and interesting to young and old alike," and that it is an "education in colour signing." Then follow instructions how to drop a penny in the slot, how to look through the lens while at the same time a handle at the side of the instrument was to be turned. We are often told by writers who profess to have had great experience that the pleasures of anticipation are more intense than the fulfilment of the coveted desire, and we lingered long over the anticipation of enjoying this feast of colour. We were about to bathe in a rainbow, and all the gorgeous tints of the solar spectrum were to come around our entranced sense. It was but five minutes to the time at which our train was to move from the platform, but still we lingered on. At last we decided

to spend the hard-earned coin, but fate was against us; we had no penny. A rush to the adjacent refreshment-room, and the purchase of an antique bun which we did not want, secured the necessary change for sixpence; and, with breathless anxiety, we dropped the fateful coin within the yawning slot, gazed through the lens, and diligently turned the handle. Awful to relate, nothing happened; the machine was out of order, and we lost both our penny and our train. We regret that we are, therefore, unable to solve the mystery of this latest apparatus for showing pictures in colour.

* * *

Concerning Inventors.

This is not a political journal, and we therefore do not concern ourselves with the merits or demerits of the fiscal system, over which just now there is such terrible ink-shed. But no one can deny that the stir that is being made, and the attention which is being directed to our methods as an industrial people, must work for good, and lead to such reforms as may be necessary. And we hope when the day of reckoning comes that there will arise some one in authority who will thoroughly overhaul our patent system. This is a question which must touch the interests of very many of our readers, for the patent specifications relating to photography are legion, and it would be an interesting thing if a profit and loss account of these documents could be compiled. One result would be certain, whatever the loss might be; a large profit would be found to accrue to the Patent Office. We are quite aware that certain reforms have been recently introduced, but the whole system requires re-organisation, for under present conditions invention, instead of being encouraged in every way by a paternal and far-seeing Government, is discouraged by the imposition of onerous taxes. The fees exacted for protection of a patent for the full term of fourteen years amount to one hundred pounds, which the inventor has to pay, in addition to the costs of employing an agent to carry through the work. In America the patent fees are seven pounds only. In a recent article in "Chambers's Journal" on "American Methods," the author, Sir Edmund Verney, speaks most strongly against our patent system. He writes:—"The English Patent Office actually wrings from the brains of wretched inventors a surplus income of £121,582 a year; and, naturally enough, there are not half as many applications for patents as in America, where there are about one thousand applications a week. American patents have given employment to enormous numbers of workpeople, and led to the adoption of much labour-saving and productive machinery. Our Patent Office ought to be at once re-modelled." We are most of us aware of the revolution in the manufacture of the photographic camera, which has been brought about by the introduction of American models, and it is a matter of constant remark that American machinery, beautifully designed for carrying out the most intricate work, is pushing its way into every other industry. A well-known tool manufacturer said to us not long ago that he no longer regarded himself as a maker of tools, but merely as an agent for the sale of those of Transatlantic origin. Surely we may say that this state of things must be due in great measure to the wise encouragement given to inventors by American legislation. But that is not all. Again quoting from Sir Edmund Verney, he writes:—"Foremen or managers in this country (Britain) generally resent suggestions from even their most practical workmen; but in America prizes of perhaps £120 a year are given for the best suggestion. The introduction of a labour-saving device or an improvement by a workman means to him a great personal advancement." It is somewhat humiliating for us to see that we

have much to learn from the wise methods adopted in such a comparatively new country as America, but the sooner we work on similar lines, and especially in the encouragement of inventive genius, the better it will be for our industries, which at present are being threatened on all sides by powerful competitors. There is a well-known story of a certain short-sighted person who killed a goose which had the very commendable faculty of laying golden eggs. Manufacturing devices and processes are the golden eggs upon which depends an industrial people's welfare, and we are killing the producers of those treasures when we tax the poor inventor. The goose story is a fable, the story of strangled invention is unfortunately true.

SOME ADVANTAGES OF RAPID EXPOSURES.

THERE has been much argument and discussion as to the comparative merits of slow or rapid exposures, in cases where it is equally feasible to adopt either. For a long time the pictorial photographer at least was wont to pin his faith to a generous exposure and a rather dilute developer, claiming that they afforded negatives of greater softness and delicacy. Of late, however, there has been evident a decided tendency to recede from this position, and a growing fondness for rapid exposures. The fact is that the photographer is becoming more and more aware of the admirable qualities of modern fast plates and films, and of certain advantages accruing from their use with large diaphragms and quick-acting shutters. The old question of hand versus stand camera does not come in here. The question under review is the advantage or disadvantage of a short exposure, without any reference to the kind of apparatus employed. What is often felt to be a strong argument in favour of the rapid exposure may be stated as follows. A finished photograph conveys a fixed and definite impression which does not alter as we look at it. Unlike poetry or music, which possess the power of calling variety and change to their aid, a picture or photograph has to make its appeal, once and for all, at the first moment the eye gazes on it. Our after sensations are purely mental processes, following slowly but surely after that first rapid glance. Now, it may certainly be argued, with considerable reason, that an impression which is to be instantaneously received, will be best if portrayed with equal quickness. To explain our meaning. When we gaze admiringly at a landscape, we do not see it in perfect rest; however still the air or constant the light, there is bound to be a swift succession of hardly perceptible changes which prevent our eyes from tiring of the scene. We cannot show this in a photograph, nor can the artist in a painting. We can only watch carefully for one suitable instant when everything satisfies our eyes, and try as best we can to preserve this happy moment on our sensitive film, so that the beholder who sees our picture may enjoy a portion at least of our own pleasure in the original. It follows, logically enough, that as we can only portray the landscape as it appears for a fraction of time, and as also the photograph so produced must make its destined effect on the mind of the beholder in much the same brief interval, that the long exposure is, in theory at least, undesirable, because instead of giving the simple impression that is wanted, it attempts to show the eye, in one short instant, more than it would naturally see in that period of time.

Among the indirect advantages of the quick exposure must be cited the fact that it generally involves the use of a large aperture and a rapid plate. These are both highly desirable from an artistic point of view, owing to the greater softness and better rendering of tone values thereby

ensured. The old-style photographer who stopped every thing down to F64 and preferred a slow emulsion, is now seldom met with. It may be stated, with a fair amount of justice, that much of the delicacy and charm of modern photographic work is due to the great advance in the manufacture of plates and films of high rapidity. It goes without saying that while, in the majority of cases, the photographer can exercise his choice between a rapid or a slow exposure, there are many instances where the former is imperative. In such a class must be placed the portraiture of children, rapidly-moving objects, animals, etc. Now, how often it is demonstrated that the operator who habitually gives rather slow exposures will secure his best and most telling pictures from just these very subjects, where his usual plan cannot be followed. He is compelled to do, for once, what he would be wise to do always, and his work is instantaneously better. It is not difficult to call to mind many examples of second- and third-rate photographers, whose ordinary productions are, although technically passable, distinctly stiff, but whose portraits of children, for instance, leave little to be desired. They would tell you the latter were prettier and more effective subjects, less difficult to pose, and so on. Of course, this would be true to some extent, but still, behind everything else, the thoughtful examiner into the reason of things would be able to see, unmistakably, that the enforced rapid exposure had really the most to do with the result.

Not that quickness of exposure cannot be overdone, so becoming a curse instead of a blessing. This latter effect is most likely to happen in the case of quickly-moving objects, and seems more or less unavoidable. It is surprising what a clumsy and unattractive picture may be obtained photographically from such a subject as a galloping or jumping horse, which no doubt will appear to the eye the ideal of grace and flexibility. In the instantaneous photograph, however, the rounded curves become straight and angular, the flowing muscles appear taut and strained; even the very effect of motion seems either lost or caricatured. It is easy enough to understand how this happens. The camera presentment is truthful and exact, but it is not what the eye sees. Owing to the phenomenon of persistence of vision, for which humanity ought certainly to feel grateful, we are unable to distinguish closely between a series of rapidly-succeeding movements, but perceive them blended together and softened to a great extent. In consequence, that crudeness and stiffness which are rendered in the camera's version of rapid motion are rarely present to our actual sight. From this, it may be deduced, as a general rule, that in the case of moving objects it is always advisable to give the longest exposure possible without showing movement. A reasonably good light is imperative if a quick exposure is to be given. This opens out another direction in which the rapid exposure seems to score. It is obvious that wherever the light is capable of modification by the operator he will naturally try to obtain as effective an illumination of the subject as possible. This leads to more consideration being given to securing a suitably even, soft, and diffused light, and, in consequence, to better pictures. The man who habitually uses slow plates and gives a longer exposure can afford to be less particular. It is not suggested that he necessarily will be, but the balance of probability points that way. Then again, wherever there is the opportunity of choosing time and place, the photographer who pins his faith to the rapid exposure will most likely determine on that period of the day, and that situation, which he knows will afford him the most satisfactory lighting; whereas one who adopts the contrary system of exposure is under no such obligation, and will take things more easily—a practice which does not tend to the finest results. It

ould certainly seem that the adoption of a rapid exposure, the standard for ordinary work, tends to the development many photographic virtues. There is yet another. It is hardly to be denied that, whatever additional effects it may have on the average worker, it will certainly promote the exercise of a faculty for instant decision. Few qualities could be of greater value in the pursuit of the camera art. The man who fumbles and hesitates is immensely handicapped. It will take him, perhaps, half a day and many failures to secure the same result that his quicker and more decisive colleague will obtain in a few minutes. This has been strikingly exemplified of late years in high-class portraiture. The methods of working of most of our best operators, as compared with the slow, experimental mode of the past, afford a striking and instructive contrast.

An old dictum, and one not even yet quite dead, is that prolonged exposure in portraiture a better and more characteristic effect is produced, through the imperceptible blending of different expressions. This is hardly a theory which finds much favour among the modern school of operators. It is perfectly true that, in the old days, the practice often had the useful effect of banishing from the sitter's face that unhappy fixity of feature produced by the use of the head-rest, and treatment which tended to promote self-consciousness. In that respect the long exposure did undeniably tend towards greater naturalness. Nowadays, however, the sitter is handled in such a different and more sympathetic manner, that it becomes simply a question of catching the rapidly fleeting smile, or the glance of interested intelligence, before they have had time to evaporate. And here, again, the rapid exposure prevails. Another direction in which the rapid exposure has beneficial consequences is to be found in those subjects where a danger of halation is present. This defect is, in all cases, less likely to occur, and very often is greatly diminished, by giving a short exposure in preference to a long one. A quick exposure does not necessarily mean under-exposure. The latter should be avoided at all hazards. It is the one great bane and curse of the photographer's existence. It ought in the majority of cases to be quite possible by wise choice of time or place, adaptation of lighting, and employment of rapid plates and lenses of large aperture, to give a minimum exposure. It need not be an instantaneous one; it is only attempted to suggest that it should be the shortest possible under the circumstances. But no matter what these may be, it must be a full and sufficient exposure, calculated to give a negative satisfactory and truthful gradation.

Mr. F. K. HURMAN, of Newcastle-on-Tyne, writes:—I have great pleasure in advising you that Mr. Tom Young, who has served us so faithfully and well since the house of Hurman opened its doors, has been appointed to manage and take charge of our Newcastle house. The many calls I have at our other branches render this development necessary.

We have received the latest edition of "Fallowfield's Photographic Manual"—a comprehensive catalogue of photographic materials, chemicals, and apparatus. It is, as usual, a most noteworthy compilation of monster proportions. Its 1,040 pages are crammed with good things, and nearly 2,000 well printed illustrations will greatly help to the vision the wavering choice of the prospective buyer, if not inveigle him into obtaining many useful things he had not heard of previously. Particulars of goods made by nearly every reliable firm in England are included, while no pains seem to have been spared to make it as thoroughly reliable in every particular. We understand that applications for more than 4,000 copies have already arrived. The price, 6d. per copy, from Jonathan Fallowfield, 146, Charing Cross Road, includes postage or carriage to any address.

THE DERBY CONVENTION.

PRELIMINARY announcements of the Nineteenth Annual Convention are now to hand, and the Derby Meeting (July 11 to 16, 1904) should prove as successful in every way as any of its predecessors. The following notice has been issued to all members:—

Dear Sir (or Madam),—Enclosed I have pleasure of handing you particulars of the Nineteenth Annual Convention Meeting, to be held in Derby, July 11 to 16 inclusive.

Derby was the scene of the first Convention (1886), when only 46 attended, and the meeting lasted but three days. Last year the membership numbered 346, and it is anticipated that the forthcoming meeting will show a still further increase.

A very attractive programme has been prepared for the week, and the excursions include some of the most interesting and beautiful scenery in Derbyshire.

An Exhibition of Members' Unframed Prints will be held during Convention week. The subjects may have been taken at any time, may be of any size, and printed by any process. A special section will be set apart for photographs taken at the Perth Meeting (1903). Should you desire to contribute any pictures to this exhibition, please let me know as soon as possible, as screens will only be provided for the exhibits of those members who have previously announced their intention of sending pictures.

I shall be pleased to forward any further particulars you may require, and hope to receive an early intimation of your intention to be present.—Yours truly,

F. A. BRIDGE, Hon. Sec. and Treas.

East Lodge, Dalston Lane, N.E.

The following is the programme of arrangements:—

Monday, July 11.—Morning and afternoon—Conducted parties to places and objects of interest in the town and immediate neighbourhood. Evening at 7.30—Official reception by his Worship the Mayor, Councillor Cornelius Boam, the members of the Corporation, and other public bodies. At 8 o'clock the President will deliver his inaugural address, after which the Exhibition of Photographic Apparatus, Pictures, etc., will be on view. Musical promenade, refreshments, etc.

Tuesday, July 12.—Excursion to Dovedale, one of the most lovely spots in Derbyshire. There will be no meeting in the evening.

Wednesday, July 13.—Morning at 10—Annual General Meeting. At 11—Meeting of the new council. At 12—The official Convention Group will be taken. Afternoon—The President, Alderman G. Herbert Strutt, J.P., and Mrs. Strutt, will give a Garden Party and Reception. Evening at 7—Annual Dinner and Smoking Concert in the Athenæum Rooms, Royal Hotel.

Thursday, July 14.—Excursion to Hardwick, one of the seats of the Cavendish family; beautifully situated between Chesterfield and Mansfield. Evening at 8.30—A Paper or Demonstration, followed by an Exhibition of Lantern Slides, by members of the Derby Photographic Society, under the direction of Dr. Collier Green.

Friday, July 15.—Excursion to Chatsworth and Haddon Hall.—The former one of the most magnificent private mansions in England, and the latter, probably the most perfect typical Baronial Castle in existence. Evening at 8.30—Papers or Demonstrations.

Saturday, July 16.—Short Excursions to Matlock, Wirksworth, Cromford, etc., etc., as may be desired.

GENERAL ARRANGEMENTS.

Place of Meeting.—The entire ground floor suite of the Mechanics' Institute has been secured for the meeting. This comprises the Albert Hall (capable of accommodating

500 persons) where the Reception, Conversazione, and Exhibition of Apparatus, Pictures, etc., will be held. The Lecture Hall, where the ordinary Evening Meetings will take place, Ante-rooms, Secretaries' Office, Ladies' Cloak Rooms, Buffet, Smoking Room, etc., etc.

Exhibition of Members' Work.—During the week, there will be an Exhibition of Unframed Prints, the work of members of Convention. The photographs may be of any size, may have been taken at any time, and may be printed by any process. A special section will be reserved for pictures taken at the Perth Meeting (1903).

Accommodation, etc.—For further particulars, hotels, private apartments, dark rooms, dealers, etc., etc., see the Official Illustrated Programme, which will be issued to members as soon as possible.

PHOTOGRAPHIC STUDIES IN THE BIOLOGY OF FLOWERS.

[A Paper read before the Royal Photographic Society.]

I PRESENT to you this evening an aspect of the art of photography which, perhaps, has not received as much notice by photographers as it deserves. Photographers, like most other people, are accustomed to treat flowers from an emotional rather than from a more prosaic and scientific standpoint. I have taken up the work for teaching purposes, and it has occurred to me that it would be more interesting to display certain facts regarding the biology of flowers by means of photographs taken directly from nature, rather than by means of the ordinary stereotyped diagrams. The series of photographs which I am about to show is rather incomplete at present. It consists partly of representations of still life pictures of flowers. About this class of photographic work I have very little to say, except that to do it satisfactorily one has to pay rather more attention to detail than is usual nowadays, when the tendency is so often to suppress detail. The scientific side, of course, has in the first place to be considered, while the artistic side of the work comes second. The other photographs in the series are mainly of sections of flowers, intended to show the structure of the flowers and their mechanisms. Lastly, I will show some instantaneous photographs explaining how insects become the agents in the pollination of flowers. The taking of these photographs is rather difficult, because in such work one has generally to use a hand camera, and yet get good focus. We cannot, of course, guess at the focus, and we have to use some sort of reflex arrangement in dealing with which we require to be more accurate than in ordinary classes of work. The only method that has been satisfactory in my work has been that depending on the use of a reflex camera; especially a reflex camera of the "Naturalist" pattern, in which the reflected image is formed in a telescope eye-piece, and can be much more accurately focussed than with the unaided eye. One, of course, has to give a shorter exposure than usual in hand camera work, when photographing living insects in active motion, and on account of the relatively large size of the image it is very liable to show traces of movement with quite rapid exposures. The size of the image further tends to give under-exposed results, hence it is advisable to use a portrait or other lens of large aperture. In the case of a portrait lens it is often advantageous to introduce slight spherical aberration to diffuse the focus. I will not say more about the difficulties connected with the subject, but pass on to diagrams showing the essential parts of flowers.

(A representation was then projected upon the screen, showing the essential parts of a flower, and particularly the pollen tubes and pistil in the centre containing the ovules.) The object of the flowers is to secure the fertilisation of the ovules, so as to produce seeds for the reproduction of the species. This is done by the transference of pollen, a yellow powdery dust from the

anthers of the stamens to the stigmas. I want you to understand that pollination is not fertilisation: the object of the flower is to secure pollination. Fertilisation, which follows pollination in flowering plants, occurs in other plants in which there is no process of pollination or production of flowers.

The pollination has to be effected by some external agency either by the wind or by some insects, and it is generally effected by the latter flying from one flower to another. Self-pollination also is possible; but cross pollination is more general. It appears that the primitive flowers of past ages were pollinated by means of the wind; but the wind is rather erratic, and this form of pollination may be looked upon as a primitive method which still survives in trees like the pine and the hazel. (A branch of hazel tree was then shown with the hanging catkins of staminate flowers, which are shaken at the slightest breath of wind.) These catkins are produced in spring, when wind is prevalent, and before the unfolding of the leaves, which would hinder the dispersal of the pollen. In the case of such plants an enormous quantity of pollen is generally produced, because a large proportion of it necessarily fails to reach its destination, so it is purely by an accident that the pollen ever gets to the stigmas. (The next slide showed two pistillate catkins of the same plant, each being a large collection of small flowers, with stigmas standing out a considerable distance, so that they might be more likely to catch the pollen floating about in the air.)

Another type I wish to speak of is that of the primitive plants pollinated by the agency of insects. Here is a specimen of the wild arum, or, as it is sometimes called, "lords and ladies." To show what can be done when the air is very still, I may mention that the plate from which this slide was printed was exposed for about ten minutes. The necessity for another method of pollination possibly arose first in the case of plants which, like the arum, dwelt in spots sheltered from the wind. Insect pollination is, of course, much more certain than wind pollination.

Another photograph showing more distinctly the inflorescence axis of the plant is now before you. Sometimes the insects are attracted by the bright colours of the flowers; but in other cases where there are no such colours, by the smell of the plant. The next picture illustrates the inflorescence cut open, showing the arrangement inside. The principal feature is a ring of projecting hairs, having passed which, the insect is shut in so that it may deposit the pollen, conveyed from other flowers, upon the stigmas below. A further slide shows the interior of an old inflorescence, the stamens having shed their pollen, and the imprisoning hairs withered, allowing the insects to fly away. The next slide shows how the willow, a plant originally intended for wind pollination, attempted to adapt itself for insect pollination. Then follow two interesting instantaneous photographs of bees visiting willow catkins. These photographs gave me a good deal of difficulty, for they were taken in March, when, of course, it was windy and the light poor; in one case the proboscis is just seen as the insect is in the act of sucking the honey. In these instances the exposure was one-hundredth of a second, and the lens set to about $f/3$. About twenty plates were exposed, only two, however, those from which the slides were taken, being presentable.

I now pass to flowers which are pollinated exclusively by insect agency. Firstly, there is a wood anemone, taken amid natural surroundings. Next we have a smaller group on a large scale, showing the essential parts of each flower. These flowers are brightly coloured, but with no honey, and attract insects by colour and by their plentiful pollen. A group of water lilies which follows has a large number of stamens, for they are essentially pollen flowers rather than honey flowers. In another group of water lilies to be seen in the next slide, the flowers stand out of the water, instead of floating upon the surface, as in the previous group. I also show a photograph of a lotus lily, such as grows so largely in China and Japan; and the same flower taken with a telephotographic lens, and, of course, much

enlarged. As they become more highly modified peculiar changes are to be found in flowers. (An example of a class of flowers which attracts insects by their large quantity of honey was then shown, followed by a representation of the dog-rose and specimen of the black thorn, showing the stamens getting lower and fewer as honey got more abundant. The next flower shown, the abutilon, was not adapted for insects, but for birds, such as the humming bird.)

The tendency of the stamens in this class of flower is to project in a long column so that the stamens may touch the wings of the birds as they hover over the flowers.

We will now pass on to flowers to which insects are attracted entirely by the honey, and in which the stamens are so few as to be only sufficient for purposes of pollination. In the group of hyacinths before us much of the beauty is lost through the absence of the natural colours. Plants of this kind, also, are very difficult to photograph satisfactorily, because the long, fragile stalks, even when there is only the faintest breath of wind, are scarcely ever perfectly still. The plate from which this slide was printed was exposed on one of the stillest days one could hope for; the flowers hang over and downwards, so that the honey may not be washed away by the rain. The next slide shows how an insect obtains the honey from one of these flowers. There was no need in this particular case to take an instantaneous photograph, because I was fortunate enough to catch the insect fast asleep after it had had a heavy meal.

We now come to flowers having long, narrow, tubular corolla adapted for pollination by insects with long tongues. The instantaneous photograph upon the screen shows an insect with its proboscis down the corolla of a flower, gathering the honey. Coming then to the primrose, I would point out the little marks on the petals, termed the "honey guides." Whenever an insect sees these little guides it at once knows where the honey is to be found. Particular attention should be paid to the two forms of the primrose flower, found on different plants, and to the fact that Darwin has shown such difference of form is to secure the cross pollination of the flowers. In the violet, a flower of rather different shape, the honey is in a little "spur," into which the small "honey guides" point. In the pea flower the pollen is "dusted" on to the underside of a bee when the insect alights on the flower to gather honey. The slide which follows shows how this arrangement is not quite perfect, for a butterfly seen visiting the flower and pushing its proboscis through and sucking out the honey without effecting pollination. (The fox-glove, adapted for pollination by the humble bee, followed by representations of two fox-glove flowers, cut open at different stages of growth, was then shown.) In the younger of the two flowers we see the stamens beginning to burst and shed their pollen. The tubular flower is the same size as the body of a humble bee; hence by the mere act of entering the flower the insect's back is sure to touch the stamens, and the pollen will be carried off. In the older flower the style is seen hanging down and the stigmas open, acting as little scoops to scoop the pollen from the back of the bee. The drawback to the arrangement is that any small insect can crawl into the flower without touching the anther or stigmas, and thus steal honey without effecting pollination. Hive bees have been seen to crawl into the flower, along the stamens and style, and thus effect pollination by their ventral surface, and not, like the humble bees, by their dorsal surface. Further observations are required to show how far this is usual.

Another example, the snapdragon, has a device to exclude those insects which are useless for purposes of pollination. The next slide shows such a flower with a long tubular body and a small mouth, to open which some little force is necessary; and a snapshot which I was able to get is seen a humble bee just entering a flower. Small flies, and apparently hive bees, are unable to effect an entrance, and the hive bee often steals the

honey by biting a hole in the bottom of the flower, thus stealing the honey without effecting pollination.

A German botanist has described a flower which keeps off creatures attempting to steal honey in this fashion. In this case the flower has a little receptacle of water around the base of its corolla, and when a bird, for instance, pecks a hole in the outer portion of the flower, a jet of water is squirted into the bird's face, and so frightens it away. The next slide shows the honeysuckle, with very long honey tube, and stamens standing out a considerable distance. Although a certain popular song associates the honeysuckle with the bee, the bee, as a matter of fact, has very little to do with the flower, for it is pollinated chiefly by long-tongued hawk moths. Even though the moth be hovering some distance away from the flowers the stamens are so long that the wings of the insect catch the pollen and so effect the pollination. The honey tube in this flower is fairly full in the evening, but generally almost empty in the earlier hours of the day; so that the bee going home at a respectable time misses the honey, while the moth is able to obtain it in abundance at late hours.

(A photograph of a caterpillar of one of the moths in question was then shown, and the little horn at the end of the insect's tail and the stripes on its back—supposed to keep off its enemies—were pointed out. The next slide showed the chrysalis of the same caterpillar, with the skin which had been cast beside it; and then the moth which afterwards emerged from the chrysalis. The slide which followed showed very distinctly the insect when dead, with its proboscis stretched out to show its great length.)

The most extreme specialisation is attained among the orchids, which often have complicated arrangements, but can only be pollinated by one species of insect. Such excessive specialisation, however, proves disastrous if the particular insect required becomes exterminated or even reduced in numbers. Another set of flowers has been evolved, adapted for the visits of any kind of insect. Such flowers are generally small, and collected into groups or inflorescences. The chief advantage of such an arrangement is that cross pollination is much more certain and rapid than if the flowers are large and some distance apart. (The points in question were illustrated by the elder, the guelder-rose with the outer flowers of the inflorescence conspicuous but sterile, their use being to attract insects to the inconspicuous central fertile flowers; and the most perfect arrangement of all in the daisy and its allies. A slide was shown of seven ages of the sunflower, dissected out from an inflorescence, showing how cross pollination was effected with rapidity and certainty by any kind of insect.)

To illustrate the variety of insect visitors, I show a specimen of a peacock butterfly visiting a sunflower. The great difficulty in photographing such objects is that a large aperture has to be used, for only a very short exposure can be given, and one is obliged, in a second or two, to get the axis of the lens as nearly as possible perpendicular to the insect. In such work I find it necessary to make as sure as possible of the parts of the object which require most attention, and trust to the other parts coming out satisfactorily. Another slide shows a cockchafer eating the outer flowers of a daisy inflorescence, and, by the act of walking about, pollinating the inner flowers; and the next photograph illustrates humble bees visiting a similar plant, the exposure in this instance having been only 1/100 of a second. (The very efficient arrangement found in such flowers for distributing their fruit was then described; and the fruit of a goat's beard shown, with its little "parachutes," by means of which the fruit was carried off by the wind. The last slide showed a butter-tree plant, bearing an extensive crop of such downy fruits.)

In conclusion, I would point out that such flowers as are adapted to the visits of all insects, and also have efficient means of seed dispersal, are by far the most numerous; that

while the struggle for existence in civilisation ends in a victory of the specialist, in the world of nature, or at any rate the flower world, the victory is, so to speak, with "the all-round man."

B. H. BENTLEY, M.A., F.L.S.

SOME SPECTROSCOPIC NOTES ON TRICHROMATIC PHOTOGRAPHY.

I.

THE following digest is considerably abbreviated, but as—so far as I am aware—no notice has yet appeared in any English journal, and the subject is one which is attracting, and deservedly, some considerable attention at the present moment, it may be agreeable to those who are interested in the process; and the high reputation of the author, Dr. Josef Maria Eder, is sufficient to invest it with some authority. The original was a paper read before the Imperial Academy of Sciences of Vienna in 1902, and is published as a special reprint under the title of "Spectralanalytische Studien über Photographischen Dreifarbendruck," and a very good colour chart and some excellent photogravure spectrograms are included. These, however, cannot, of course, be reproduced.

E. J. WALL.

The most important process of colour reproduction by photography is the subtractive method, by the superposition of yellow, red, and blue printing inks, either by colotype or typography. The usual printing inks are chrome yellow, krapp lake or alizarine red lake, and Berlin blue, generally known as Milori blue.

The solar spectrum is generally divided by the aid of filters into three zones, which approximately correspond to the physiological primary colour sensations. The blocks from the negatives thus produced are printed in inks complementary to the colour filters through which the negatives were produced.

If the filters recommended by theorists are spectroscopically examined, it will be found that they may be divided into three main classes:—

(a) From the red to D, from D to about F for the green, and thence to the blue violet.

(b) Or the spectrum is divided into similar zones but with overlap on both sides.

(c) Or the opposite method is adopted and the three zones are so much narrowed that there are vacancies in the yellow and blue green regions.

As the theorist has rarely supported his statements by sufficient practical typographic or collographic tests and the practical worker has kept his methods of working a close secret, the author has for years made a study of the subject, and his spectroscopic results (theoretical) have been substantiated by empirical tests (practical) in the printing department of the K.-K. Lehr- u. Versuchsanstalt at Vienna, and as excellent results were obtained the author gives his researches for publication.

If an ideal panchromatic plate were obtainable, that is, one which was equally sensitive to all the spectrum rays, the problem would be considerably simplified, as suitable filters would merely have to be found; but, unfortunately, all existing panchromatic plates are unsatisfactory, as they show drops in colour sensitiveness, and, when spectroscopically tested, irregular maxima and minima.

If separate plates are used for the green and blue violet sensations, exactly similar conditions occur, and as, for example, the yellow-green plate should be equally sensitive to yellow-green, green, and blue-green, it frequently happens that the yellow sensitiveness is so predominant that a "dampening" filter is essential.

A quartz spectroscope and a metallic concave grating were rejected, and a direct-vision spectroscope composed of three prisms, by Steinheil, was used, and the comparison curves of a

single prism and the three-prism spectroscope are very similar if not identical.

For orientation of the wave-lengths, the lines of sodium and thallium, the magnesium-spark spectrum, the lithium flame and lithium spark were used, and for the ultra-violet the author's alloy of equal parts of cadmium, lead, and zinc, and also some iron lines were used.

Spectroscopic tests must, for three-colour work, be backed up by tests on pigments.

The ratio between the visual luminosities of the solar spectrum and the light reflected from pigments has been frequently estimated by various experimenters, and the yellow of the D line estimated as from 9–31 times brighter than the spectrum blue, at F₂G, and from 21–87 times brighter than the dark spectrum blue at G, whilst pigmentary yellow is from 6–14 times brighter than the blue; spectrum yellow of the D line is from 19–40 times brighter than the red, between A and C, whilst with pigments it is only 3–7 times brighter.

Further, as the prismatic and diffraction spectra differ in the ratio of luminosity in the yellow and blue the above results cannot give comparable figures for photographic work.

A knowledge of the qualitatively estimated absorption spectra of light filters is not sufficient to recognise their action in polychromatic photography, for the extent of the colour zones which photographically act is dependent on the length of exposure or the intensity of the light. With short exposure only the brighter portion of the spectrum rays transmitted by the filter will exert a photographic action, corresponding to a narrow spectrum band; with long exposure the colour zones which are much dampened will also exert a photographic action. Thus with prolonged exposure, or greater intensity of light, a broader colour zone will act than with a short exposure.

This uncertainty of the action of colour filters induced the author to determine the quantitative absorption of various filters.

In the reproduction of oil paintings or of other objects behind colour-filters it is always necessary to expose sufficiently long to give details in the shadows. The limit of over-exposure (or the limit of the maximum exposure permissible) begins when the highest lights of the negative cannot be differentiated. Exposure and development must not be carried beyond a point that will, according to the reproduction process, give a density above 2–3, approximately 2.5.*

The brightest colour zone of a filter will therefore act in a normal negative so as to produce a photographic density of 2.5, and it will then be seen how far under these conditions the half-dampened colour zones photographically act. This method did not lead to absolute certainty of results, as there is always a certain latitude of exposure and development that influences the gradation of the densities; but it gave a better insight into the action of light filters than any previous method.

Repeated experiments by the author satisfied him that with very short exposures the light filters cut off photographic action where the transmitted light was reduced from 30–40 per cent. With mean exposures other zones of the spectrum came into action, and these where the remaining light intensity amounted to 10–20 per cent. Wherever a filter showed a brilliancy of about 10 per cent. must be set, practically, the photographic limit of the same. With very long exposures, bordering on the region of over-exposure, then the photographic action must be limited in any colour region to a light intensity of 5 per cent., and in this case the "density" is from 0.4 to 0.5 when the greatest density in the negative equals 2.5.

As regards the foregoing remarks, it must be assumed that the photographic plates have good sensitiveness in the desired

* The term "density" is here used in practically the same sense as used in the H and D system, that is to say, as the logarithm of the opacity. Dr. Eder uses Scheiner's sensimeter, which is very similar to the H and D, and a Hartmann microphotometer.—E. J. W.

tions, and that the zones and filter damping do not correspond with the minima of the plate sensitiveness.

It may be usually assumed in reproduction work that with sufficient exposure the vigorous image begins where the transmitted light equals 20 per cent. of that which is transmitted by the greatest maximum transparency of the filter; with a light equal to 10 per cent. behind a filter there is always given a half tone; whilst with a light equal to 5 per cent. only a very pale half tone is given which for trichromatic reproduction is not of any moment.

LENSES FOR TRICHROMATIC WORK.

The following notes on the above subject conclude Dr. Eder's paper on three-colour work, and as it is not an unimportant part, they may be of interest.

The achromatism of an ordinary objective is not sufficient for three-colour work, and it is easy to determine how a lens could be corrected from the spectroscopic examination of the spectra and filters. With the orange filter the lens should be corrected in the red for the characteristic lithium line λ 610, the hydrogen line $H\alpha$ λ 656, the Fraunhofer line C.

For blue-violet the achromatism may be somewhat wide. The particular sensitiveness of gelatino-bromide of silver extends from λ 400-425, with a glass apparatus and generous exposure it extends from λ 490-HK in the ultra-violet, so that the optician can choose from λ 450 to λ 440, or from $F\lambda$ 486 to $KH\lambda$ λ 393; for instance, the Fraunhofer line $G'\lambda$ 434* or $h\lambda$ 410. The latter corresponds to the requirements of a wet collodion of silver collodion, the maximum action on which begins at λ 437 and includes λ 423 and λ 410, and which is specially suitable for half-tone and line-work on account of its good definition and sharpness of the lines.

For ordinarily achromatised lenses, which are almost always made with gelatino-bromide plates, it is practically immaterial whether the focus of the D line λ 589 coincides with the blue hydrogen line $G' = H\gamma$ λ 434, or with the violet calcium line $g\lambda$ 423 or $h\lambda$ 410. For reproduction photography with wet collodion the correction for mean violet ray $g\lambda$ 423 is the best.

All opticians do not correct for the same rays, as is obvious from the accompanying table, the details of which have been supplied by the firms in question:—

T lenses are corrected for			
Ordinary lens, Steinheil	D λ 589	...	g (Ca) λ 423
Trichromatic lens, Steinheil	C λ 656	...	F λ 486
Photographic lens, Steinheil	$g\lambda$ 423	...	λ 389
Ordinary lens, Voigtlander-Harting	D λ 589	...	G' (Hy) λ 434
Ordinary lens, Zeiss	D λ 589	...	G' (Hy) λ 434
Correct for chemical rays only it should be according to Voigtlander	F λ 486	...	λ 434 & $h\lambda$ 410
Trichromatic, Voigtlander-Harting	C λ 656	...	F λ 486
Refracting double anastigmat, Series III.	D λ 589	...	G λ 434
Refracting apochromat, Series IV. †	D λ 589	...	G' λ 434

For the green filter the principal action is represented by the magnesium line $b_1\lambda$ 517, and the apochromates should be corrected for this ray. The opticians do not specially correct this green ray, but for orange and blue, and assume that correction for the green will be sufficient. For blue-violet rays, or when using photographic plates which are only sensitive to these rays, the following considerations are worth taking account: If collodion plates without a light filter are used, excellent negatives of the blue-violet region may be

obtained with the Steinheil achromatism for λ 423, which corresponds with the middle of the principal action of the ordinary violet filter, with which the printing plate for yellow is prepared.

The apochromat for three-colour work should be corrected for

Orange at the Fraunhofer line	C λ 656
Orange at the lithium line	λ 610
For green at the Fraunhofer line	$b_1\lambda$ 517
For violet at the Fraunhofer line	g Calcium λ 423

Unfortunately the region from λ 656- λ 423, which is of importance in tri-chromatic photography, is too great to be altogether corrected, even if glasses are used, which diminish the secondary spectrum; therefore the narrow correction of the region from the orange line to the blue line λ 434. This should extend from λ 610- λ 434. A better correction would be from λ 656- λ 423, but practically if it extends to λ 486 it is sufficient.

Two excellent process lenses were tested, by focussing for each colour midway between the axis and the margin and the aberration from the focus of the D-line estimated. Both gave the same amount of aberration, but one was much worse than in the violet, the other equally as bad in the violet as the other was in the red. Practical experiments with three-colour prints showed that the latter objective, which was better in the red than the violet, gave undoubtedly more precise three-colour prints than that which was worse in the red than in the violet, which gave a marked fuzziness of the prints.

This result will not be a matter of surprise to the expert in colour-printing, for the yellow printing plate, produced by the blue-violet rays, is printed first and is more generally a coloration film; whilst the blue printing plate, produced by the orange-red rays, which is printed last, gives, according to the colour printer, not only the contour, but the drawing of the picture. Therefore it is of less moment if the yellow printing plate is less sharp if only the red-and-blue plates are sharp and superimpose well.

MESSRS. GEORGE HOUGHTON AND SON, LTD., of 88 and 89, High Holborn, London, W.C., write:—We have much pleasure in informing you that we have incorporated the business carried on by us as George Houghton and Son, Ltd., in succession to George Houghton and Son (established in 1854), with those of Messrs. Joseph Levi and Co., 97, Hatton Garden, E.C., wholesale opticians and photographic dealers; Messrs. Spratt Bros., Tudor Works, Tudor Road, Hackney, manufacturers of photographic and scientific apparatus and instruments; Messrs. Holmes Bros. (Sanderson Camera Works), Park Street, Islington, N., photographic apparatus manufacturers; Mr. A. C. Jackson, Hex Camera Works, Northwold Road, Stoke Newington, N.E., photographic apparatus manufacturer. The style of the new company will be "Houghtons, Limited." The combination of manufacturing and distributing interests of which the new company will consist will place us in the position of being the largest manufacturers of photographic cameras and apparatus, as well as the largest distributors of photographic goods generally in Great Britain, and, we trust, will enable us to meet the ever-increasing demand for British-made cameras and apparatus of all kinds. Mr. George Houghton will be the chairman of the new company, and Mr. M. L. Isaacs (J. Levi and Co.) the vice-chairman. The active management of the amalgamated businesses will remain in the hands of the members of the several firms who have for so many years past conducted them so successfully, our Mr. E. W. Houghton and Mr. C. E. Houghton taking an active part in the general management. For the present the various businesses will be carried on exactly as heretofore. As soon as practicable, however, arrangements will be made to simplify the distribution to the mutual advantage of our customers and ourselves, and in the meantime we shall, of course, be glad to enclose with our goods orders for goods of any of the amalgamated businesses.

The hydrogen line G' must not be confounded with the Fraunhofer line $G\lambda$ 4307 which is an iron line.
This lens is corrected for D and G' , but the glasses are so chosen that C, F, and G' are practically corrected.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE third annual dinner was held in the Victoria Hall of the Criterion Restaurant on Friday, the 11th inst. Mr. Alfred Ellis (President) occupied the chair, and amongst the company present were Mr. Thomas Bedding, F.R.P.S. (past President), Mr. Wm. Grove (past President), hon. secretary and treasurer, Mr. T. C. Turner, of Hull (Vice-President), Mr. P. E. Marshall (hon. solicitor), Mr. and Mrs. F. A. Bridge, Mr. S. H. Fry, Mr. H. Edmonds (Hull); Mr. Louis Langfier, Mr. H. S. Mendelssohn, Mr. E. Scamell, Mr. Lang Sims, Mr. W. Downey, Mr. and Mrs. H. Snowden Ward, Mr. and Mrs. Alec. Corbett, Mr. and Mrs. H. A. Chapman (Swansea), Mr. and Mrs. Daniel Prodger, Mr. and Mrs. Edward Cherry (St. Albans), Mr. Warwick Brookes (Manchester), Mr. T. Birtles (Warrington), Mr. H. Pumelle (Leeds), Mr. Frank Turner, Mr. E. J. Walker, etc.

An excellent menu was done ample justice to, after which the customary loyal toasts were given and duly honoured.

The President, who was received with cheers, said he had the honour and pleasing duty to propose the toast of the evening, that of "The Professional Photographers' Association," or, in other words, their good selves. This was the occasion of their third anniversary, as in March, 1901, their Association was founded. Although not progressing by leaps and bounds, he was pleased to be in a position to inform them that it was going on steadily and successfully, and it was seldom a week passed without bringing applications for membership from some portion of the country, and in time, therefore, they might reasonably hope to be the proper representative association of professional photographers in Great Britain and Ireland. This was the first occasion that ladies had been introduced to their meetings of this nature—(hear, hear)—and although he regretted the number was not greater, he could assure those ladies present that he was very pleased to see them, as he knew that in photography ladies were a great help to their husbands, and it was therefore only fair that they should share with them the pleasures of a meeting of this description. During the past week many letters of apology and regret had reached him from members who were unable to attend, and he had just received a telegram from one of their vice-presidents, Mr. W. Crooke, of Edinburgh, heartily congratulating them, and regretting his inability to be present. Another telegram had also been received from their old friend and fellow-committeeman, Mr. Martin Jacolette, who unfortunately, through illness, was prevented from attending, but who sent his best wishes for a pleasant evening, while regretting he could not be with them.

The two principal items which the Association had undertaken for the current year were an exhibition of professional work and a scheme for an examination for photographers' assistants. The exhibition of professional work would be held at Derby in June, during the Photographic Convention. The Corporation of Derby had kindly placed their picture galleries at the disposal of the Association for a month, and the committee were very anxious that their exhibition of pictures should be the very best that professional photographers could produce, and he therefore trusted that the members would strive to make the exhibition a great success. The suggested examination of photographers' assistants was a very important matter, and one which would require a considerable amount of care and thought. A number of meetings of the sub-committee appointed would therefore be necessary before the scheme could be perfected and launched, but he was sure that they would eventually carry it through successfully, and that it would rank as one of the best things done by the Association.

Passing from this subject, the President said he would like to address a few words to the members with regard to the duties of the officers of the Association. They had a very good committee, and they had worked excellently during the past three years. It could not reasonably be expected that they could continue doing this work, and therefore he appealed not only to those members present that evening, but to all those who would read an account of this meeting in the *BRITISH JOURNAL OF PHOTOGRAPHY*, to give their greatest attention to the voting for the new committee at the annual general meeting, and he hoped they would, at any rate, interest themselves in the work the present committee have initiated. If the members do not interest themselves in his direction, the Association would not go forward in the way they wished. He also trusted that every endeavour would be made to increase the membership. At

present their finances would not permit of it, but he should like to see a permanent office of the Association, at which any member could call and consult the assistant secretary, or whoever was appointed to represent the Association there, upon any matter which might crop up. At the present time it was somewhat awkward, and people thought he could see them at all times of the day or answer their inquiries by telephone. It was obviously impossible for him to do this, and he hoped that with increased membership it would be possible to obtain what was desired, and thus have a permanent address. It was also essential that they should increase their membership on other grounds. Their present membership of 600 was but a small one, seeing that there are approximately 6,000 photographers in the United Kingdom, and if at any time it became necessary to approach Parliament on any question, it would not be very effective unless the Association was in every way a representative one.

He would ask them to drink to the success and prosperity of the Professional Photographers' Association, coupled with the name of their esteemed hon. secretary and treasurer, Mr. Wm. Grove.

Mr. Grove said he had much pleasure in responding to the toast. He could truly say the Association was prospering—(hear, hear)—and deservedly so, considering the amount of energy put into the work by both the London and Provincial committees, and as a result the Association was proving its usefulness both to its members and the profession generally. The fact that some ninety new members had been made since June last was tolerably good evidence of the vitality of the Association; but he thought they must not rest content with they had at least a membership of over 1,000. The work of the committee during the past year had been made familiar to them through the medium of the *BRITISH JOURNAL OF PHOTOGRAPHY*, and in regard to this they were under a deep obligation to Mr. Bedding, their past president, for his kindness in placing his journal at their disposal. (Hear, hear.) He did not think he could do better than read a memorandum contained in their invaluable handbook regarding the work of the Association, viz.: "Many hundreds of letters have been replied to asking advice or information upon such subjects as Right of Copyright, Infringed Copyrights, Trade Terms, Discommodities, Right to Negative, Charges for Special Work, Studio Construction, Price Cutting, etc. In many cases the advice given has resulted in preventing fruitless litigation, and in others it has undoubtedly assisted in obtaining satisfaction, with or without going into court. The expert evidence that is available to a member is often invaluable."

With regard to this, he felt it right to say that he would like to have received greater acknowledgment from the members to whom such advice had been tendered.

There was another matter to which he might be allowed to draw their attention with advantage to themselves, and that was the liberal terms afforded the Association by the Fine Art Insurance Company, which conceded to members a 20 per cent. reduction on premiums hitherto paid. The cheap methods of enlargement schemes had engaged the serious attention of the committee with good and wholesome results. He was pleased, in his position as hon. treasurer, to inform them that there had been a steady increase in the Association's bank balance, and they might consequently congratulate themselves upon the position arrived at.

The President had referred to the importance of members attending the annual general meeting. He quite endorsed all that had been said in that direction, and he found that there were about 110 members whose residence afforded them easy access of attending that meeting, and also the members' meetings. If they would do so, it would be a graceful recognition of the committee's labours, as some of that body came long distances, such as from Hull, Colchester, Tunbridge Wells, Brighton, etc.

Mr. Lang Sims, who apologised for "chipping in," said the committee had entrusted him with a very pleasing duty, i.e., to present to their past and present presidents solid gold badges suitably inscribed. These gentlemen had done, and were still doing, extraordinary good work for the Association. He would explain the term extraordinary. The first president, Mr. Bedding, started the institution and made it an extraordinary success; Mr. Grove, who followed as second president, was treasurer 1901-2, president and treasurer 1902-3, and treasurer and hon. secretary 1903-4; Mr. Alfred Ellis was hon. secretary 1901-2-3, and president 1903-4. The London committee thought that they would like to make them a little present. When

is mooted the country members said, "No, you don't, unless we are allowed to chip in too," and he must tell them that so popular was the idea that the whole of the committee had joined hands. There had been some fun over it, and considerable discussion as to who was to make the presentation, but eventually it was decided that the best-looking man was to do it. But even then jealousy was rife, and it was difficult to decide who possessed this qualification, as the best one had little hair but good features, and another a tolerable amount of hair but no features, and they saw in him the compromise. (Laughter.) He had, therefore, much pleasure in making the presentation, and he would ask the gentlemen concerned to accept the medals as a small token of goodwill from the committee, and he felt sure that the members of the P.P.A. would like to be included in their good wishes. (Cheers.) His injunction had been that he was to make a presentation gracefully, and he trusted he had succeeded.

In suitable words Messrs. Bedding, Grove, and Ellis returned thanks for the handsome mementos of office.

In a happy and breezy speech, with occasional poetic flights, Mr. A. Bridge proposed the toast of "The Ladies," to which, on their behalf, Mr. H. A. Chapman, J.P., responded.

Mr. S. Herbert Fry, in proposing the toast of "The Local Branches," said that in view of the fact that there were approximately 6,000 photographers in the country as against 600 in London, the country members must be considered the very rock bottom foundation of the Association's success. As they were aware, there were a certain number of local branches already established, and it was the ambition of the committee to see sooner or later the formation of a branch of the parent body in every town of the country, and thus promote good fellowship among photographers as a body; and they felt that unless they could bring about unity and strength amongst photographers their work would be very slow. The committee was, therefore, particularly anxious not only that the present organisation of the Association should continue, but that it should be increased in efficiency, and that its branches should spread everywhere. There was always the tendency of the country members to think that the London members have matters all their own way respecting what is done on the Council. If one really came to examine the question, the town members are very much less in need of the Association than are the country members, and that was why in proposing the health of the local branches they felt that it was in a sense necessary to urge upon their country members the necessity for exertion among themselves. Everything could not be done from London, and country branches were therefore essential. Mr. Turner, whose name was coupled with this toast, had set a fine example of what could be done by a local branch if it really put its back into it. They knew the Hull branch had been very keen and long on this matter, and had shown the London Committee a very good lead as to what could be done by energy and enterprise with a certain tendency towards retaliation, notably in connection with the Oxo Free Portrait scheme. He had much pleasure in asking the country to drink to the continued prosperity of the local branches, coupled with the name of that energetic organiser, Mr. T. C. Turner.

Mr. Turner, who was received with cheers, expressed his thanks on behalf of the local branches. Mr. Fry had said more than they deserved—certainly more than he deserved—and he felt that these branches were capable of doing very much more good work in the future. All the towns in England had unfortunately not realised the good which might be done in the direction of the formation of local branches, which were the means of getting photographers together and persuading them that they had certain specific duties to do, and interests to safeguard. The photographer's voice in Hull counted for something, and they did not intend to allow aspersions on their profession to pass unchallenged. When one considered the many photographic studios throughout the country, representing an enormous amount of capital, it did not seem to mention the clever business energy displayed by some of the best photographers in the kingdom, it was not likely that they were going to sit down quietly and allow such reprehensible practices as were recently foisted upon them, as, for instance, the Oxo Free Portrait enlargement, etc. It was no use for members to simply contribute a subscription to the Association and then cry out, "What is the good of the Association?" They wanted something more than the subscription of 5s.; they wanted the more cordial professional feeling, and when this was obtained the Association would become a great force for good. He hoped that before long the spirit shown in London would be copied in a dozen centres in the country.

Mr. Fellowes Wilson proposed the toast of "The Officers and Committee," and Mr. Louis Langier responded.

Mr. W. Downey proposed "The Health of the Visitors," coupled with the name of Mr. E. J. Walker, the designer of the beautiful menu card.

Mr. Walker briefly responded on behalf of the visitors, and thanked Mr. Downey for his kind remarks.

In proposing the toast of "The President," Mr. Bedding said he was inclined to quarrel with their toast list, as he was of opinion that the present toast should have been included with the third toast of the evening, viz., "The Professional Photographers' Association." He was sorry that on this occasion Mrs. Ellis should have been unfortunately prevented from being with them, and he was sure that Mr. Ellis felt her enforced absence very keenly. He had the honour and pleasure to propose the health of Mr. Ellis, their President, and in doing so he would couple the name of Mrs. Ellis. Mr. Ellis was the third occupant of the presidential chair, and his sincere hope was that he would continue to retain it for many years to come.

Mr. Alfred Ellis, who on rising was received with acclamation, said he thanked Mr. Bedding very much for the kind way in which he had proposed his health, and the members for the hearty manner in which they had responded. If he had one regret that evening it was that his wife was not beside him, owing, he was sorry to say, to the serious illness of one of his children. She had looked forward to this meeting for months past, and her inability to be present was a great disappointment to her and also to himself, as he would have liked her to hear all the kind words said of him. He felt he could not take all those kind words to himself, because he had someone who assisted him day after day in the work of the Association. He alluded to the Assistant-Secretary, Mr. Mackie, who was also unfortunately prevented from being with them owing to a family bereavement. Without Mr. Mackie he felt sure the work of the Association could not be carried on in the prompt and ready manner in which it is performed. Mr. Bedding had said he was a busy man, but he was able, with Mr. Mackie's assistance, to take up any matter which reached him by letter the first post in the morning, and during the day to send, if necessary, some sort of answer or advice to the member seeking assistance if it was a matter of any considerable moment. They did what they could at the time, or if unable to themselves, would call together a few members of the committee residing near and consult with them if found necessary before the whole of the committee met. The business is, therefore, attended to promptly. While, therefore, he thanked the company for the hearty manner in which they had drunk the toast, he would ask them to drink Mr. Mackie's health and success. This was done with cheers for Mr. Mackie.

The pleasant evening terminated by the company singing "Auld Lang Syne."

During the evening an excellent entertainment was provided by Messrs. Walter Churcher, Otley Cranston, Edgar Coyle, J. M. Campbell, and Herbert Townsend (accompanist).

We have received a copy of the new 1904 illustrated catalogue of the Altrincham Rubber Company, in which will be found a complete list of photographic specialties, comprising shutters, lenses, cameras, shutter accessories, rubber goods of all kinds, carrying cases, back-grounds, bromide printing machines. A copy will be sent free of charge from the head office, Mossburn Buildings, Altrincham, to anyone interested.

The programme of a photographic excursion to Bruges is to hand from Mr. W. F. Slater, F.R.P.S. The excursion will extend from March 31st to April 5th, 1904, and Ostend, Ypres, and Ghent will also be visited. Mr. Slater will personally conduct the trip, which is a sufficient guarantee for its complete success. As on previous occasions, the excursion is under the auspices of the South London Photographic Society, whose successful exhibition was brought to a close on Saturday last. An excursion will also be arranged during the Whitsun holidays to Zealand, and one, two, or three weeks' excursions will be provided for during the summer to Holland, Germany, and Switzerland. Those intending to take advantage of these photographic outings on the Continent should write for full particulars to Mr. W. F. Slater, 68, Longhurst Road, Hither Green, S.E.

NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

THE annual general meeting of the National Photographic Record Association was held on Wednesday, 9th inst. At the invitation of Sir J. Benjamin Stone, M.P., President of the Association, the meeting was held at the Midland Grand Hotel, St. Pancras, and tea was served to a large assembly of members and persons interested in the work of the association, among whom we noticed Sir J. Benjamin Stone, Sir C. Purdon Clarke, C.I.E.; Sir Alfred Haslam, M.P.; Major-General Waterhouse, C.I.E.; Major C. C. Bard, Mr. and Mrs. Snowden Ward, Messrs. George Scamell, Hon. Secretary of the Association, L. Fletcher, F.R.S.; and C. E. Fagan, of the British Museum; H. B. Wheatley, F.S.A.; A. Graham, F.S.A.; G. A. T. Middleton; A.R.I.B.A.; Alfred Ellis, President P.P.A.; J. W. Marchant, Alexander Mackie, Horsley Hinton, F. R. Armytage, J. W. Tapley, H. W. Fincham, E. Goodman, W. T. White, Rev. J. O. Bervan, George F. Parkes, Dr. R. H. Mill, etc.

The annual report showed that satisfactory progress had been made during the year, 683 prints having been received, making a total of 3,142 valuable records deposited for reference in the British Museum since the foundation of the association. During the year Sir J. B. Stone has again been a liberal contributor, having presented a complete series of the Coronation ceremonies, including portraits of many of the celebrated visitors and Colonial troops. Also records of various festivals, such as the Eisteddfod held at Bangor, 1902; Clipping the Church at Painswick, Gloucestershire; May-Day Ceremonies and Crowning the May Queen at Knutsford, Cheshire; the Pole Fair, Corby, Northamptonshire; Collecting the Commoner Penny at Hock Tide, Hungerford, Berks; the old mansions of Littlecote, Wiltshire; Holkham Hall, Norfolk; and a selection of photographs of Christ's Hospital and Newgate Prison. Mr. Bingley has contributed a fine series of views of Stonehenge, and of the colleges of Oxford and Cambridge, and some of the old houses of St. Albans, Lavenham, Suffolk, and Huntingdon, including the old school where Cromwell was educated. Mr. Fincham has contributed a set of Castle Acre Priory, Norfolk; the Round Church, Little Maplestead, Essex; and remains of the old Roman Wall and foundations of the New Gate at Newgate; Mr. J. W. Marchant, a set of Bury Hall, Lower Edmonton, the residence of Bradshaw, the regicide; and Salisbury House, also at Lower Edmonton, residence of Judge Jefferies; from the Rev. J. K. Dixon has been received a particularly interesting collection of some of the old London signs, including the Crown and Three Sugar Loaves, A.D., 1660, Fenchurch Street; and the Dog Head in Pot, A.D., 1509, Blackfriars Road; from Mr. E. Godman, views of Caerphilly Castle, Glamorganshire, and of Castle Heddingham, Essex; from Mr. A. V. Haslam, a series of 15 of Haddon Hall; from Mr. J. G. Mortimer, views of Star Castle, etc., Scilly Isles, being the first photographs received from this district; Mr. Woodfall has forwarded a set of the Old Post or Windmills of Essex; Mr. Davison has presented a set of Malmesbury Abbey, and of the Manor House, Upper Upham, Wilts; Captain Cosens, Memorial Crosses, etc., from Llanbadarn-Faur Aberystwyth; Miss Lucy E. Beedham, views in Cambridge, including the Round Church; Mrs. F. H. Gandy has contributed views of Thrumpton Hall, Notts, Kedleston Church and Hall, Derbyshire, and other views; Miss J. Niblett, some interesting details of Stretton Sugwas and other Churches, Herefordshire; and miscellaneous views have been sent by Messrs. J. E. Longbottom, J. H. D. James, A. Cheese, F. Hayward, J. Murdock, C. E. Knowles, H. T. Malby, C. Upton, J. W. Andrews, S. J. Beckett, H. B. Dutton, E. Scamell, and a series of Churches in Hertfordshire and Middlesex by the Hon. Sec., George Scamell.

A satisfactory feature of the report is the reference to the increasing interest taken in record work by county and local record associations. Among the organisations acting with or on similar lines to the National Association, the Survey and Record of Surrey, under the presidency of Viscount Middleton, Mr. H. D. Gower, Hon. Secretary, have now collected nearly 1,000 prints, which have been deposited in the Public Library, at Croydon, Mr. I. S. Jast acting as curator. The County of Leicestershire have a thoroughly well-organised survey, Major W. I. Freer, V.D., F.S.A., president, and Mr. A. Roehling, M.I.C.E., secretary. Herefordshire, under Mr. A. Watkins, president, and Mr. C. Gethin, hon. secretary, have now some 300 prints, which are deposited in the museum at Hereford. Dundee and East of Scotland Survey, Mr. B. Hatch, hon. secretary, are working that section of the country, and prints are deposited at the City Library, and the Town Council have voted a grant of £50 per annum for three years towards

the expenses of the survey. The North Middlesex Photographic Society have formed a Survey Section, Mr. J. W. Marchant, as hon. secretary, and have collected some interesting series of the old historical houses of North London, so rapidly disappearing before the speculative builder, and some good specimens were exhibited at their annual exhibition; other societies are at work at Ealing, Brentford, Essex, Birkenhead, Coatbridge, Somerset, Shropshire, with headquarters at Shrewsbury, Clifton, Oxford, Ipswich, Hull, and other centres. For contributions to the collection of record photographs the Association has hitherto been mainly dependent upon practical photographers, amateur and professional, but with a view of enabling the Council to provide the funds for making prints from the most important of the negatives which are available, and as some return for contributions received either in the form of subscriptions or photographs, it has been decided to publish an illustrated pamphlet on record work to be issued to all members, and if sufficient support be obtained to issue one annually. In the first number the illustrations will be of some of the old historical houses of London, several of which have already been removed, and Mr. H. B. Wheatley, F.S.A., the leading authority on the antiquities of London, has kindly contributed a note on Wych Street, Strand, lately cleared away by the London County Council on account of the Strand improvements, now in progress. In future the number of illustrations and the size of the pamphlet will depend upon the amount of subscriptions received, the present intention being to select for reproduction some of the most interesting prints received during the year.

The following were elected to serve as officers and council for the ensuing year:—President, Sir J. Benjamin Stone, M.P.; Council, Right Hon. the Earl of Crawford, K.T.; Sir E. Maunde Thompson, Sir H. Trueman Wood, M.A.; Messrs. F. R. Armitage, C. E. Fagan, H. W. Fincham, L. Fletcher, F.R.S.; A. V. Haslam, A. Horsley Winton, St. John Hope, B. E. Lawrence, Alexander Mackie, J. W. Marchant, G. A. T. Middleton, A.R.I.B.A.; Dr. H. R. Mill, Mr. and Mrs. H. Snowden Ward, and Mr. H. B. Wheatley, F.S.A.; Hon. Treasurers, Alexander Graham, F.S.A.; Hon. Secretary, Geo. Scamell, 21, Avenue Road, Highgate, N.

THE INVARIABILITY OF THE WAVE-LENGTHS IN THE SPARK AND ARC SPECTRUM OF ZINC.

[From the "Chemical News."]

II.

The arrangement of our experiments, as regards the production of the spark discharges in question between zinc electrodes, exactly agreed with those experimental conditions under which Haschek thought he had proved the existence of "line displacements." In his "Spektroanalytische Studien" (These "Sitzungsber.", 1901, Bd. cx., Abt. II., p. 200) he says expressly that the lines were displaced more with the Ruhmkorff inductor and hammer interruption, than when a similar inductor with Wehnelt interruption, or when a transformer was used. Hence, we also used powerful Ruhmkorff induction coils with hammer interruptors; we had two large inductors, striking at a distance of 12 to 25 cm., with correspondingly large condensers, so that a real displacement phenomenon could not possibly have escaped us.

But under these conditions the asymmetrical broadening phenomena of the zinc lines λ 4680, 4722, 4810, etc., appeared clearly, and in our experiments we obtained at once one of the phenomena which Exner and Haschek call displacement phenomena. Fig. I. of our heliographic table shows two zinc spectra* accurately photographed one above the other, which immediately make it clear how the "displacement phenomenon" appears. As a matter of fact, from a superficial inspection one would be inclined to pronounce in favour of a displacement of the lines, although a displacement of the true intensity maximum does not actually occur. Similar false "displacement phenomena" also appear under other different experimental conditions; if the photographs of the zinc lines are illuminated too long they present this appearance, if we produce them on the one hand with pure zinc electrodes, and on the other with zinc alloys, which only contain a little zinc, which is interpreted by Exner and Haschek as the influence of the partial pressure of the vapour; also with defective definition of the spectra, the zinc lines taken for the sake of comparison in the arc (narrow lines) and in the spark (asymmetrically broadened) generally look similar. But it may at once be stated that the two spectra in Fig. I. were obtained

* Facsimile of the original negative in-heliogravure. The figures referred to are not here reproduced; they should be consulted in the original article.—Eds. B.J.P.

one and the same zinc spark, with short and long exposure (one minute to five minutes),* and that the supposed displacement of the lines is only the photographic expression of the asymmetrical broadening of the photograph of a wedge-shaped, outlined streak of light. It shows itself with lengthened exposure, even if the intensity maxima remained quite constant. The spectra, when very shortly exposed, give only the intensity maximum of the lines which is on the blue, while with longer illumination the line of the spark spectrum shifts more towards the red than towards the side of shorter wavelengths, and with rather longer development of the photographic plate the intensity maximum of the line is united with the asymmetrical broadening. After the conditions under which the phenomenon in question appears are explained, we can pass to the description of the results of our own experiments in which those circumstances liable to give rise to error were carefully avoided. When every precaution is taken to ensure minimum illumination, the plates are correctly exposed and the spectra best defined, it appears:—

That at ordinary atmospheric pressure there occur no displacements, which are said to appear, according to Exner and Haschek, in the spectrum as opposed to the arc spectrum.

that also in the spark spectrum no displacements of the lines which were to be ascribed to small quantities of the element that in the vapour, i.e., that any dependence on the partial pressure in the sense of Exner and Haschek's assumptions cannot be proved. In both cases only the known variable asymmetrical broadenings of the lines occur, but the brightness maxima of the lines coincided exactly in our experiments.

studied the same zinc lines in which Haschek observed displacement in the spark spectrum, and first determined their wave-length as best as was practicable, using Rowland's standard, corrected by him, ("Normale aus dem Bogenspektrum des Eisense," "Ann. der Physik und Chemie.," 1900, 4 Folge, Bd. iii., p. 195); the line were then viewed under the microscope, each line at least ten times on different photographic plates, so that our wave-length observations are correct to 0.2 A.U.

According to Haschek the lines in the arc spectrum of zinc show normal wave-length, and with small partial pressure, in Haschek's experiments are better for ascertaining the normal wave-length (without any influence of the disturbing so-called "displacement phenomena"). We chose the formation of the zinc arc spectrum, brass wire (in the small arc), which according to chemical analysis contained 36.9 per cent. zinc and 63.1 per cent. copper.

The carefully determined wave-lengths of the zinc lines of such an arc spectrum, obtained by the use of brass electrodes, gave for the arc spectrum:—

Zinc—III. order				λ 3302.715
33	33	33	3303.068
33	33	33	3345.141
33	33	33	3345.698
33	33	33	3282.451
33.	II.	33	4680.327
33	33	33	4722.333
33	33	33	4810.719

the same field of vision in the arc spectrum, next to them came copper lines of the third order, λ 3247.671 and 3274.090 (Rowland). In the arc appear reversed (symmetrically broadened), while the spectrum of iron, photographed as normal, contains a trace of copper having a fine black copper line, which coincided perfectly with the phenomenon of inversion.†

The heliographic table, Fig. II., 1 and 2, shows the exact spectrum graph of the arc spectrum of a zinc-copper alloy; it is clear how increasing illumination all the lines of the arc spectrum remain sharp, and broaden symmetrically. Pure zinc gives in the spark spectrum λ 680, 4722, 4810, with increasing illumination asymmetrically broadened strongly towards the red, but with exact minimum illumination; the brightest part of the line appears sharp enough. The strongest spark from a jar to fix exactly its wave-length, and to enable to establish under the microscope its coincidence with the arc spectrum, which is evident from our table (Fig. II., 1-4). With the zinc lines λ 3282, 3302, 3345.1, we found likewise perfect coincidence in the arc spectrum and spark lines; the zinc spark lines λ 3345.1 and 3302.7 are

easily reversed, and then coincide perfectly with the (unreversed) arc line. With over-illumination a broadening of this line towards the ultra-violet occurs. The zinc line 3345.698, which is to be obtained well-defined and clear, both in spark and arc, without difficulty, and 3303.068 are considered by Haschek himself as not capable of displacement, because their tendency to remain well-defined even with inexact times of illumination prevents any error which could exist with defective definition in the case of the zinc lines 4680, 4722, etc., which broaden asymmetrically.

Fig. III. shows in Spectrum 1 and 3 the spark spectrum of pure zinc; Spectrum 2 in the middle is the arc spectrum of the zinc-copper alloy, and over all three is extended the arc spectrum of an iron wire containing traces of copper. We see the perfect coincidence of the reversed copper arc line λ 5247, and 5274 with the unreversed copper spark line. The zinc lines, λ 4722 and 4810 (Fig. III.), are rather much illuminated and developed to strong blackness, by which means the arc lines of the middle spectrum have broadened on both sides fairly uniformly, while the spark lines show a symmetrical broadening and the beginning of apparent displacements, which disappears with minimum illumination and shorter development, after which the perfect coincidence analogous to Fig. II. becomes undoubtedly evident.

In the zinc lines, λ 3345 and 3302 of Fig. III, we further see that these zinc lines in the spark, as compared with the arc lines, are by no means displaced towards the side of greater wave-length, as Haschek (loc. cit.) erroneously states. We see this still more clearly in the measurement of the original negative under the microscope of the measuring apparatus.

The supposition that Haschek had badly-defined spectra gains in probability owing to the fact that the finer structure of some zinc spark lines, which is very remarkable, escaped him. While the asymmetrical very marked broadening of the zinc lines 4680, 4722, 4810 towards the red did not escape Haschek, he did not notice that the zinc lines λ 5345.1 and 5302.7 show a tendency to slight broadening towards the side of shorter wave-length, and hence they lose the tendency to apparent "displacements" towards the red. Nevertheless, Haschek finds the lines in the spark specially strongly displaced towards the red (as compared with the arc), and we find, on the contrary, that here with correct short exposure generally no displacement, but coincidence, results.

After we had failed to establish the results quoted as relating to the line displacements in the spark as opposed to the same lines in the arc, there still remained further experiments to be arranged on the influence of the partial pressure of the luminous zinc vapour on the displacement of the spectral lines. For this purpose we subjected to an accurate investigation the spark spectrum of pure zinc and that of alloys of 1 per cent. zinc + 99 per cent. lead, as well as 50 per cent. zinc + 50 per cent. lead and 36.9 per cent. zinc and 63.1 per cent. copper. In the case of alloys poor in zinc, according to the experience of all spectroscopists, which was first published long ago and is now generally known and never disputed — and this holds good for all spectra, especially with a symmetrical broadened lines—all those lines, even with increasing illumination, remain fairly sharp, which, in alloys rich in zinc, undoubtedly show in a high degree the tendency to a symmetrical broadening. Thus far the partial pressure undoubtedly exerts an influence on the breadth of the spectral line.

Thus, with increasing time of illumination, the asymmetrical broadening phenomena in the case of alloys rich and poor in zinc are not the same; thus, if we measure on the more strongly illuminated plates the wave-length of alloys rich and poor in zinc by placing on the middle of the badly-defined lines, apparent line displacements appear with rising partial pressure (analogous to the photograph in Fig. 1.), which, however, we at once recognise as apparent displacements if we have returned to minimum times of illumination and have obtained the best defined spectra.

A 1 per cent. zinc alloy (1 per cent. zinc + 99 per cent. lead) naturally gives the separate zinc lines in the spark less clearly than one richer in zinc, e.g., a 50 per cent. zinc alloy. A preliminary test for our strongest spark (Ruhmkorff) showed that the poorer alloy (1 per cent.) must be illuminated for about fifteen minutes, as compared with about thirty seconds for the richer (50 per cent.) in order to get the zinc lines 4680, 4722, 4810 approximately equally sharp (equally bright) on the photographic plate for both alloys. Hence in our preliminary experiment in the first case the zinc lines would be thirty times brighter than in the second.

B.—The finer lines in Spectrum 1 are iron lines photographed in. The brass electrodes were used directly for the production of the arc. In agreement with these experiments of ours, Exner and Haschek, in their "Verlängertabelle," Bd. 1, p. 21, speak of the two copper lines 3247 and 3274 as liable of being displaced.

If, now, we use equivalent times of illumination and approach the minimum time of illumination, which in both cases gives faint, just measurable lines in the spectrogram, in the spark spectrum the wave-lengths of the zinc lines 4680.327, 4722.333, and 4810.719 in 1 per cent., 4 per cent., and 50 per cent. alloys, and in pure zinc, are exactly the same, and we could never—even with the strongest jar spark—see Exner and Mache or Haschek's "line displacements."

Haschek (These "Sitzungsber.," Feb., 1902, Bd. cxi., Abt. II.a, pp. 238 and 240) states that alloys with a little zinc (4 per cent. zinc) give in the spark spectrum zinc lines of wave-lengths λ 4722.399, but with 50 per cent. zinc this becomes 4722.434, which would be a considerable displacement towards the red with increasing partial pressure; he finds the zinc line 4680 in alloys poor in zinc (4 per cent. zinc) too faint to be measured. But this line 4680, even in 1 per cent. alloys, can be measured (this is shown clearly in our table, Fig. IV., 4) if we choose the time of illumination properly. Haschek has obviously under-exposed the alloy poor in zinc and over-exposed the richer alloy, and was deceived by an asymmetrical broadening of the lines with defective definition of his spectra. As far as we can see, Haschek applies his theory of displacement only to a symmetrically broadened lines; with the sharp lines not even the apparent displacement of the lines is to be seen in the spark spectrum as opposed to the arc spectrum.

Thus our results are:—

1. In the spark spectrum of zinc, as opposed to the arc spectrum, no displacements of measurable magnitude appear.

2. The mass of the elements present, or the partial pressure of its vapour, produces no displacement of the lines of the spark spectrum, and hence Haschek's system of quantitative spectral analysis falls to the ground; on the contrary, those conclusions which presuppose the constancy of the spectral lines (displacements of the spectral lines in the radius of vision according to Doppler's principle, etc.), and which appeared doubtful owing to Haschek's deductions, are further confirmed by our observations.—"Sitzungsber. der Kaiserl. Akad. der Wiss. in Wien," Bd. cxii., Abt. II.a, October, 1903,

J. M. EDER.
E. VALENTA.

THE OLD SOUTH LONDON PHOTOGRAPHIC SOCIETY AND THE NEW.

[An address delivered at the opening of the Exhibition of the South London Photographic Society.]

I FEEL very much the compliment that your society has paid me by asking me to come and formally declare this exhibition open. I feel a peculiar interest in the South London Society, because it has succeeded—at all events, in name—to the society with which I was myself connected a good many years ago. I think it was somewhere in the early eighties that the old South London Society finished. Perhaps I ought to remember the date better, because I was president at the time of its demise. Whether it was the fact of my being president killed it, or whether it was so moribund that not even the fact of my being president could save it, it is not for me to say. It died after having done excellent work, and it has been succeeded by the present most flourishing society. When one thinks of these things one cannot help contrasting the difference in matters photographic in the early ages with what they are now. For my part I think that photography then was a great deal more interesting than it is now, and for this reason: Those of us who attempted to produce photographic work at all had to do practically everything for ourselves. We know how things are now. At the time I was speaking of gelatine plates had just been invented, and were being commercially put on the market, but I know we did make plates for ourselves. Now, I do not suppose there are very many of you ladies and gentlemen who have ever made a gelatine plate, but I can assure you that when you have spent a good many hours, a good many evenings in making a batch of plates, you have got a good deal more pride, a great deal more interest in the plates than you could possibly obtain from the plates you purchase now. I am afraid they cost us a good deal more, because when I think of the percentage of failures in plates, and in the drying (the drying was a horrible nuisance), I fancy that probably a whole plate must have cost me (some of my friends were more skilful) about 2s. 6d. a plate, and you were disposed to be more careful of those plates than you are now. It was a period of great anxiety and hard work. At that time (I looked up the matter in the BRITISH JOURNAL the other day) I see there were, I think, just a dozen photographic societies in Great Britain and Ireland. At the present moment there are, I think, 266. I think my memory serves me rightly,

but I only counted them once. The work we did in those days in old societies was of very great value. In those times the people who did the experiments were really the amateurs, and I know we were all of us useful to very many professional photographers, who were always willing to give us any tips they got, because the amateurs were perfectly ready to work them out if they could, and they were not likely to make any improper use of them. Amateurs in those days were really amateurs, and there was a very distinct line between those who carried on photography merely for pleasure and those who made it a matter of business. I am afraid the line is not now so strictly drawn. I think this is a matter for considerable regret. A great deal of the scientific progress in photographic matters has become a matter of trade interest and the manufacturers of plates and papers very naturally and very properly do not care to take the world, as their rivals, into the confidence as to the manner in which they make the very beautiful plates and papers which are now at our disposal. I do not suppose there are half-a-dozen amateurs (people unconnected with photographic manufacture) in this country who really know how the most rapid and best gelatine plates are made. I only know one amateur who does—my old friend Sir William Abney. Except for him I doubt if anybody could undertake to produce a high-class plate which would compare with those now made. If photography, therefore, is now more of a commercial matter than it was, I think the main objects of such a society as this are to prevent it becoming so entirely. I do not know what proportion of the people who use cameras develop their own plates and films. I am inclined to think that the proportion is really a small one. I do not speak, of course, of those photographers who form members of a society, but I mean those we meet with at the hotels, where almost every other person has got a camera, and who generally shirk the work of developing their films. This is not as it should be. Do as much as possible of the work yourself; then you are entitled to some credit. In the other case you are not entitled to any credit at all. An old friend of mine (he was a good deal older than I am myself, and I don't profess to be a chicken) went to Egypt for a month, and thought he would like to take some photographs. He took a camera and a large amount of films. The other day he proudly told me that he had exposed 33 pictures. He called them pictures! He evidently thought he had done a very good month's work. This is not the sort of work we want to encourage. I am sure the real good work which the societies do nowadays is to keep up the standard of photography—scientific and pictorial photography—by meeting and discussing among themselves the best methods of getting the work done. The old South London Society was killed by tobacco and drink. Not because of these two enjoyments, but because of the absence of them. The old society used to meet in the Society of Arts' Rooms in the Adelphi, and drinks were not provided at that establishment, nor was it possible to arrange for smoking; and a good many photographers in those days used to like a little of something to drink during the evening when talking, and were also fond of smoking. The consequence was the South London Society was practically succeeded by the London and Provincial Association, which owed its success to more convivial methods. I do not know whether the members of this society are anti-tobaccoists, or whether they look after themselves during their meetings, but if they do not, I think they would do well to do it. I congratulate you most heartily upon the very fine collection of pictures which has been brought together. It is a new thing for the society to get together a fine collection; and I am sure I can speak from experience, for I saw one collection of yours a few years ago, and I was struck with what I saw. This appears to me quite as good if not better than that. I can only congratulate you most heartily upon the success you have achieved, and hope you will regard it as an encouragement to persevere. The side of the room containing the pictures of the members seems to me to hold its own against the side of the room which is open to all the world. This is a thing of which you ought to be proud. I am not quite certain that what used to be your speciality—the architectural interiors—is quite so striking now as it was a few years ago; but I suppose you have more or less exhausted that field for your own amusement, and you have gone on to others, and you have reason to be proud of your landscape pictures. You have listened to me very patiently, and I am now only keeping you from the inspection of the pictures, and from the collection of apparatus which is here as well as pictures. I do not think I ought to detain you any longer except to close by congratulating you heartily upon the success which you have achieved, and I hope that that success may only be an encouragement to you to do similar work in future years.

SIR H. TRUXMAN WOOD, M.A.

THE EVOLUTION OF AN INDUSTRY.

[From the "Barnet Photographic Record."]

When we hear, as we do almost daily, of decaying trades, of closed factories, and of discharged hands, it is cheering to be able to turn instances of the opposite, which we are glad to think are not so few and far between as the most pessimistic fiscal prophets are inclined to believe. There are British trades which can show a history manifesting in its own way quite as rapid a growth, and a far more solid one, than some of the much-lauded American ventures. How many of the users of the "Barnet" products, for example, give thought to the extent of the operations of which they are the result? In the belief that a few details on the point will be without interest, the following table may serve as a concrete example of the evolution of a purely British industry.

1878.—The silver printing business started by Mr. J. J. Elliott.

1880.—Carbon printing, enlarging, and tissue making undertaken.

1881.—Dry plate making commenced.

1883.—Bromide enlarging started; the dry plate factory doubled in size.

1889.—A new plate factory put up, and coating and other machinery introduced.

1890.—The "Barnet Extra Rapid" plate first made.

1891.—The "Studio Plate" put upon the market.

1892.—Flat celluloid films introduced.

1894.—Bromide paper making added, and a special factory constructed for the purpose. The "Rocket" plate produced.

1895.—The "Barnet" lantern plate first made.

1896.—"Barnet P.O.P." put upon the market.

1897.—The third dry plate factory erected, with electric lighting and power plant, and a new factory for the manufacture of bromide and P.O.P.

1899.—Another factory for the manufacture of carbon tissue, built and fitted with entirely new and up-to-date machinery.

1902.—The fourth plate and paper factory constructed.

1903.—The "Barnet" roll film introduced.

Such a record is one of which a Briton may well feel proud, and if we are asked to account for so strong and vigorous a growth, we believe we could put our finger upon one particular spot, and say that therein lay the germ of the popularity of the "Barnet" products of the past, and our hope of their still greater favour in the future. That spot would be the laboratories in which all day and every day trained staff is employed exclusively on the testing of the quality of the materials made. In no manufacture is this so absolutely important as in photography, where the user relies often upon the quality of goods, the defectiveness of which—if they were defective—could only be discovered when it was too late to remedy. For that reason, then, we realise that, given a good article at the outset, its absolute reliability is the thing that is to make it known and appreciated; and, that being so, no labour or expense within reason is too great to secure such an end. But a captious critic might say, "Yes! you have told us all about your new factories, your electric installation, and your carbon tissue, but what about their output? A shed six feet by six may be dubbed a factory, and sound enough in the ears of those who have not seen it." Well, then, here are some figures which may give our friend an idea of the capacity of his "sheds." Let us take the case of plates first, of which ten different brands (and, alas! how many different sizes) are manufactured. The combined capacity of the last two plate factories erected is one hundred thousand half-plates per day, weighing about eight tons. Over and above this there are two kinds of films and two of roll films for negative purposes. Then, in the case of papers, we have (excluding carbon tissue) nine kinds of wide paper, ten of P.O.P., and four of gaslight papers. How many kinds of carbon tissue we make is hard to say offhand, but we make no less than fourteen. The last bromide paper factory has an output of 12,000 ft. of paper 42 in. wide, equal to three hundred seventy-five thousand quarter-plate pieces per day.

Now, to produce all these, there are in constant employment four steam engines, two steam engines, four gas engines, three dynamos, eleven electric motors, six hot-water boilers, and six fans (the largest are 18 in. in diameter). Seven cutting machines are occupied in cutting the paper, some of them being of the latest rotary type, while the plates are cut by special machines, each of which will divide

seventeen whole-plates into quarters in one minute. The "Barnet" goods will be found in use in every country in the world, for professional portraiture, by amateurs, and for trade purposes, not to mention the scientific applications to which they are put. The Astronomer Royal employs them for the great chart of the heavens now in process of formation; they are also used in the Antarctic expedition. The items connected with publicity in connection with the "Barnet" products are in themselves almost staggering. Between eight and ten tons of showcards are sent out annually, exclusive of packing, the "Barnet" book has run through seven editions, making in all 50,000 copies, the "Barnet Handbook" goes out at the rate of 100,000 copies a year, with no signs of cessation, while the issue of the "Record" totals up to 270,000 per annum. To secure freedom from defects, the site was chosen amid the pure country air of Hertfordshire, in the fields by Hadley Wood, near the quaint old coaching town of Barnet, where *Oliver Twist* thought every other house seemed to be a public-house. Yet even this precaution—the country air, not the public-houses—is not sufficient, and all the work-rooms are supplied with air filtered through cotton wool to exclude the smallest particles of dust. Over and above the strictly manufacturing side of the business at Barnet, there is, as readers of the "Record" know, the printing and enlarging work in which the factories took their origin. These have gone on and grown with the rest, until we find six enlarging rooms for carbon and bromide work, together with the many other requirements of that particular side of the business. Our sketch would not be complete without some mention of the department which is to the rest as the brain is to the human body—the research laboratory. Here are all kinds of elaborate appliances such as science is constantly putting at the disposal of industry—spectroscopes, photometers, microscopes, balances, and countless forms of physical and chemical apparatus. But we have surely said enough to convince our sceptical friend of the nature and extent of the buildings, the erection of which we noted in the chronological table.

A few words more, and we have done. This complicated organisation, in which all is done that elaborate applications of mechanics, chemistry, electricity, and optics can do to supplement and assist human skill, has as its final outcome—what? No intricate maze of wheels and levers, no mighty engine that can drag three hundred tons as many miles in a few hours, no delicate and costly fabric that may ultimately clothe a queen. It is represented in its simplest form by a quarter-plate, costing the sum of one penny, a mere square of glass coated on one side with a mixture of gelatine and a salt of silver. But that compound represents the substance that is of all the most delicately sensitive to outside influences of the slightest character, and in that penny plate lie potentialities of human pleasure of which the mightiest monarchs of the past could have no conception. It may be flung away—the failure of one who will never learn; but perchance it will serve to keep green the memory of a loved one who has gone, and show us features we can never otherwise behold again—an artificial, inanimate, but indestructible memory.

THORIUM for Radiant Energy.—What is stated to be probably the first instance of a photograph being taken by the emanations from thorium was recently exhibited at the Röntgen Society. Mr. H. Lacy exhibited a negative taken by means of the emanations from the thorium contained in an ordinary Welsbach mantle, which had been cut and spread out flat, two coins placed upon it, and covered over with a sensitive dry plate. The whole was then wrapped up and put away in a safe, and at the end of thirteen days the exhibitor found that he had obtained a good negative.

LENGTHENING the Usefulness of the Electric Glow Lamp.—The filament in glow lamps gradually diminishes in diameter in consequence of the slow volatilisation of the carbon. According to the "Elektrotechnische Rundschau," a German firm introduces into the glass globe certain chemical compounds with a high boiling point; these, under the influence of the temperature in the lamp bulb, slowly give off vapours containing carbon, which is deposited on the filament, thus making up to a large extent for the loss referred to above, and keeping the resistance and also the brightness of the lamp more uniform throughout its useful life.

Exhibitions.

NOTTINGHAM CAMERA CLUB.

THE above exhibition, opened at the Mechanics' Institution, Nottingham, on the 11th inst., is quite up to the average as regards the pictorial value of the exhibits, while the technical element is of a high standard throughout. No less than 37 awards, divided amongst ten classes, have been made by the judges (Messrs. Harold Baker, Birmingham, and W. R. Bland, F.R.P.S., Duffield), the proportion of awards to exhibits comes out at one in ten, with one over for the champion.

In the Champion Class, pictures previously medalled, we were pleased more particularly with Mr. Etches' "Wengern Alp," a bromide of good tone and marvellous softness and beauty; while No. 23, a carbon by J. C. Batkins, entitled "The Hill Side," is by far the most pleasing in its vicinity. It is seldom we can see a figure study of this quality so instinct with life and so free from the suspicion of artificial posing. There are many pictures in this class deserving of detailed notice, notably "The Village Ford," Graystone Bird; "The Pool," C. E. Etches; "Welcome Evening," J. C. Batkin; "On the Hill Side," F. Pinder; No. 61, "A Gleam of Light," deservedly secures a silver award here, and no one is likely to cavil at Mr. Clayden's success with this fine work. A local man, Mr. Arthur Marshall, shows his carbon study, "The End of the Day," a picture in the Robinsonian vein and suffering little by comparison with a work which is historic; and we finish off with Mr. Harold Barrett's "Hunting Scenes," a class of work which, no doubt, brings in more money than exhibition fame.

The light on this side of the room does scant justice to the really admirable work shown. No. 49, for example, "The Brook," by Douglas Deeling, suffers terribly from this cause; look at it how we may the impression is that of a sheet of khaki-coloured paper, with a streak of white across the middle distance. It is only fair to assume there is a *raison d'être*, some foreground, and suggestions of detail, but it is impossible to tell with accuracy. It would be a great improvement to hang the frames on screens and place them at right angles to the wall.

The colour of print achieved by most of the exhibitors in carbon and bromide is pleasing and undeniably successful throughout; the effect is, we think, not a little discounted by the prevailing, not to say universal, method of mounting in glazed frames. Many of these pictures would show up better without the glass, and, having written that, we suddenly arrive at No. 93, "Rufus," a study in carbon (sepia), by F. Pinder, which turns out to be very nearly what we had in mind. This print is mounted upon a raised stained wood block, with a deep bevel, and—nothing else! The effect is very good, however, though this style of block mounting is not to be commended for general adoption. Good stout boards are to be had, the surface of which could be prepared by pasting thereon a suitably tinted art paper, and on this the print would be mounted and prepared for the frame, with no fear or tendency to cockling.

The Architectural Class is very strong, not only in the open, but also the members'. In the former Mr. Percival W. Crane scores with "Crypt de l'Aquilon, Mont St. Michel," a difficult subject treated with great skill, and is closely followed by Mr. F. J. Phillips with "The Chapel of Our Lady of the Undercroft, Canterbury," who also receives recognition. Mr. Edwin Halley demonstrates that Nottingham is not far removed from similar beautiful subjects of ancient architecture. Mr. Thomas Wright has some fine examples of his work in the Members' Class, "The Sentinels," "The Fisherman's Home," and "March Winds" being worth more than passing notice; in fact, Mr. Wright's positions in the prize list must not be taken *au sérieux*. Mr. Arthur Marshall's work here calls for special mention, though, on the whole, we rather prefer this gentleman's portrait and architectural work, in which classes, as will be seen, Mr. Marshall scores heavily—and properly.

The following is a full list of the awards:—

OPEN CLASSES.

Class A.—Champion Class: Silver gilt plaque (No. 1), John C. Warburg.

Class B.—Landscape, Seascape, and River Scenery: Silver plaque

(No. 61), W. Clayden; silver plaque (extra) (No. 27), John C. Warburg; bronze plaque (No. 20), Chas. E. Etches; certificate (No. 76), S. W. B. Vines.

Class C.—Portraiture, Figure Studies, Animals, and Still Life: Silver plaque (No. 109), Furley Lewis; bronze plaque (No. 113), Furley Lewis (debarred); bronze plaque (No. 104), Furley Lewis (debarred); bronze plaque (No. 108), F. J. Mortimer; certificate (No. 115), Miss Cecily Adams.

Class D.—Architecture and any subject other than Classes B and C: Silver plaque (No. 158), Percival W. Crane; bronze plaque (No. 154), Francis J. Phillips; certificates (No. 171), A. A. Bellingham (No. 163), S. G. Kimber; (No. 159), Alfred J. Loughton.

Class E.—Stereoscopic Work (set of four prints): Silver plaque (No. 8), Harry Wormleighton; bronze plaque (set No. 9), Harry Wormleighton (debarred); bronze plaque (set No. 6), F. G. Tryhorn; certificate (set No. 5), T. G. Hibbert.

Class F.—Lantern Slides (set of four, any subject): Silver plaque (set No. 26, slide 1), F. G. Tryhorn; bronze plaque (set No. 9, slide 1), Wm. Clayden; certificate (set to 23, slide 3), Wm. Mosley.

MEMBERS' CLASSES.

Class G.—Landscape, Seascape, and River Scenery: Silver plaque (No. 218), Will Darcy; bronze plaque (No. 183), R. R. Enfield; certificates (No. 205), Will Darcy (debarred); (No. 190), Thos. Wright (No. 222), Arthur Black.

Class H.—Portraiture, Figure Studies, Animals, and Still Life: Silver plaque (No. 268), Arthur Marshall; bronze plaque (No. 266), R. Chapman; certificate (No. 269), S. D. Middleton.

Class J.—Architecture, and any subject other than Classes G and H: Silver plaque (No. 287), Arthur Marshall; bronze plaque (No. 292), E. H. Atkin; certificate (No. 284), Percival W. Crane.

Class K.—Lantern Slides (set of four, any subject): Silver plaque withheld; bronze plaque (set No. 35, slide 4), Henry Crowdon; certificates (set No. 40, slide 1), Arthur Marshall (debarred); (set No. 42, slide 3), William Mosley.

Special Award.—Silver gilt plaque for the best picture by a member of any society affiliated to the R.P.S. (No. 109), Furley Lewis

G.E.R. MECHANICS' INSTITUTE.

THE photographic section of the Great Eastern Railway Mechanics' Institute held its eleventh annual exhibition at the Institute, Stratford E., on the 8th and 9th inst.

Although the exhibitions of the Great Eastern Railway Mechanics' Institute are hardly on the plane of rivalry with those of the important metropolitan societies, they are always interesting to us, as an index to the progress of untutored photography. We do not mean untutored in its literal sense, for the section has the advantage of the tuition of Mr. H. W. Bennett, than whom the members could have no better guide in practical photography, and in the elementary principle of its application to pictorial work, but rather in the sense of photography which is not or but little influenced by the passing fashions of the hour. The work generally of the members was as unambitious as that shown half-a-dozen years ago. The craze for enlarging everything seems not to have infected the Stratford photographers, and the various ways of toning bromide paper are apparently still untried. The average size of the pictures in the exhibition was much less than one finds in even small exhibitions of society work nowadays; half-plate pictures were plentiful, and even the modest quarter-plate print was not infrequent. But in spite of the modest character of the work as regards size and boldness of attempt, we are pleased to be able to report a very decided advance in a most important direction. The work generally gave evidence of very much greater care in selection, of better technical photography, and more taste in the get-up of the prints. A few rather florid frames there were truly, but they were the exception. From among the collection we could select quite a number of little pictures which, in the days when work of the kind produced by Colonel Gale was considered worthy of the highest admiration, would have received more than passing notice had they appeared in one of the leading exhibitions. Such work is no less commendable now, although modern taste is in the direction of bolder treatment and greater freedom of style.

In the two classes which comprised landscape, seascape, and river scenery, "The Mill, Evening," "A Misty Day," and "Early Autumn," by W. Salter; "Hopforth Wood," and "Dividing Ways," by A. Woolford; and "The Meadow Gate," "Russet Autumn," and "Anchored,"

A. Cracknell. "By the Zuyder Zee" and "The Willow Bank," by A. Smith, were particularly good. Quite a large class of architecture contained many carefully chosen and well rendered examples, including "The Font," "Jesus Chapel," "The Bridge," and "The Angel," all at Norwich Cathedral, by P. J. Perry; "Chichester Cathedral," by L. C. F. Robson; "Interiors in Exeter and Peterborough Cathedrals," by A. Woolford; "Choir and Nave, Salisbury," by E. Ayling; and "South Choir Aisle, Chichester," by T. A. Smith. Engraving reached but a very low ebb, but several of the fruit and flower studies in the same class were very good indeed. "Cankers and Oakspray," by A. Woolford; "Flowers and Fruit," by E. Ayling; "Dessert and Sweet Peas," by W. Salter, amongst the best; and "Shoeing," by P. T. Perry, perhaps was the best animal study. In a small beginner's class E. J. Chapman showed promise. The class for engineering and mechanical subjects did not show any particular aptitude on the part of any of the exhibitors. We certainly think it a pity that the branch of photography in which, from their opportunities and mechanical knowledge, so many of the members are in a position to make a mark, should be neglected. Besides the proportion being useful and even valuable, the technical skill required, in photographic manipulation and in the treatment of the subjects, is to show their salient points, provided the best possible exercise those faculties which are essential to success in all branches of photography.

A small open class of pictures contained a few interesting works. The judges were Messrs. J. T. Ashby and E. Marriage, for the general class, and Mr. J. Holden, M.I.C.E., M.I.M.E., for the engineering class.

THE AWARDS.

MEMBERS' CLASSES.

Landscape.—Silver medal: A. Salter; bronze, A. Woolford; commended, T. A. Smith.

Architecture.—Silver medal: P. J. Perry; bronze, A. Woolford; commended, L. C. F. Robson.

Landscape and River Scenery.—Bronze medals: A. Cracknell and W. Salter; commended, T. A. Smith.

Portraiture, Flower, and Animal Studies.—Silver medal: W. Salter; bronze, H. D. Banks.

Engineering and Mechanical Photographs.—Bronze medal: H. D. Banks.

Lantern Slides.—Silver medal: T. A. Smith; bronze, A. O. Shave; commended, A. Woolford.

Beginner's Class.—Bronze medal: E. J. Chapman.

OPEN CLASSES.

Landscape.—Silver medal: Rev. H. R. Campion; bronze, J. Bruce; commended, A. Woolford.

Lantern Slides.—Silver medal: F. Parkinson; bronze, Graystone; commended, A. Woolford.

Stereoscopic.—Bronze medal: H. Wormald; commended, F. P. Wormald.

tones a good colour. We understand that this paper does not contain an excess of acid-preservative, but, nevertheless, keeps excellently, and in view of the fact that photographers, particularly of the higher artistic school, are reverting to albumen as a printing medium

possessing a characteristic delicacy and atmosphere not to be found in any of the other printing out papers, it is likely to enjoy much popularity.

Some new developing dishes have likewise been put on the market recently by Messrs. Griffin. The "Iltz" dish (Fig. 1) is an entirely new model for plate development. It consists of a strong, deep dish, with two wells, one on each side of the dish. This permits the immediate lifting of the plate from the solution without any plate lifter. When once used, its convenience is readily apparent. The Ribbed Papier-maché dish is also likely to commend itself (Fig. 2).

Fig. 1.

Fig. 2.

Fig. 3.

The usual form of papier-maché dish has a flat bottom, making it very inconvenient for use with plates owing to suction between the plate and the dish. This difficulty is now overcome by the two ribs at the bottom of the dish. The "Cellulite" (Fig. 3) dish is an extremely light and portable dish, but made of extremely hard material. Quite unbreakable, and not liable to crack. All these dishes are very inexpensive.

The Southport Enlarging and Copying Table and Screen.—Sold by Sanders and Crowhurst, 71, Shaftesbury Avenue, London. W.C.

The table is fitted with fold-up legs, adjustable to uneven floors. On the top of the table grooves are provided, and at one end of these is the carriage for the lantern. The base-board of the lantern sits on this carriage, and by that means can be pushed up to, or away from, the screen (at the opposite end of table) to give the various degrees of enlargement. The lantern moves in a plane at dead right angles to screen, and cannot get out of the straight.

The screen is of novel construction. The front is glazed with plate glass, and opens on hinges like a book. Behind the plate glass front, and in contact with the glass, is a white focussing cardboard screen. The cardboard is ruled off to the usual photographic sizes, from 15 x 12 down to 4 1/4 x 3 1/4. The frame is so held in a carrier that it has horizontal, vertical and circular motions. A horizontal or vertical picture can at once be projected on the focussing cardboard, and a correct idea of how to enlarge the picture may at once be formed. The carrier is held by a screw attachment at its back, the screw passing through a strong bracket, and the bracket being hinged at its base. By a quick release, this bracket with carrier can be moved back (on its bottom hinges), so that it lies flat on the table end. The front of the frame can then be opened while lying in a horizontal position, and the bromide paper put in flat, so that it lies within the ruled lines. The plate glass front should then be

New Apparatus, &c.

Simple Print Trimmer, etc.—Sold by John J. Griffin and Sons, Limited, 20-26, Sardinia Street, Lincoln's Inn Fields, London, W.C.

This is a useful tool for photographers in the shape of a print and trimmer. It is well made, of heavy metal, and the cutting edge is capable of making a remarkably clean cut with either paper or thin cards. We can confidently recommend this as doing all that is needed for it, and it will be noticed that the base-board is ruled in inch squares to facilitate the trimming of prints, etc. We have had submitted to us specimens of a new bromide paper of excellent quality, which has been placed on the market under the name of "Griffin's Bromide Paper." It appears to be produced from a solution especially adapted for making enlargements. It is of fair density, and yields prints with rich blacks and good whites.

This enterprising firm is also exploiting the old favourite albumen printing process. Samples to hand of the 'Climax Sensitised' Paper show a carefully prepared production which prints easily and

closed and clamped, and the bracket, with carrier and frame complete, may be pushed up to the exact position at which focussing was performed, and the exposure made. For daylight enlarging the lantern is removed from the carriage, and a camera, the actual one

with which the negative is made may be used, placed there instead. By pushing the table against the darkened-out window, unclamping the screen bracket, and sliding the screen up and down the guides, the degrees of enlargement may be obtained. For copying photos, engravings, manuscripts, etc., they may be placed in the frame, and the camera brought up to it. Special frames are built to order, for every purpose, such as holding old books or large deeds, etc. The apparatus complete, to enlarge from $\frac{1}{4}$ plate to 15×12 , is comparatively inexpensive (lantern extra), and packs up flat into a parcel about 6ft. long \times 18in. wide \times 6in. deep. The screen can, however, be obtained in other sizes or separately. This firm is also responsible for the "Birdland Camera—an ingenious instrument of the Reflex

focal plane type—made to the specifications of Mr. Oliver G. Pike, the well-known bird photographer. The camera is specially designed for the natural history photographer, and appears to be a thoroughly efficient camera for the work. The plate may be placed in the camera and carried about all day ready for exposure at an instant's notice, and focussing can be done up to the moment of exposure. It embraces a long focus (four times the length of the plate), and while focussing with one hand it is possible to instantly release the shutter with the other. This camera, designed for such a purpose, should prove as valuable a companion to the naturalist in his country rambles as a field glass.

Wynne's "Infallible" Shutter Speed Tester.—Manufactured by the Infallible Exposure Meter Co., Wrexham.

There can be no doubt that a reliable and not too complicated an apparatus for accurately testing and recording the speed of the photographic shutter would fill a long felt want. Such an instrument has now been placed on the market by Messrs. Wynne, which appears to do in a satisfactory manner all that is claimed for it. There are not many shutters put on the market which have speeds marked on them correctly, and it is the function of this piece of apparatus to place in the hands of the amateur or professional a means of finding out what the various speeds given by his shutter really are.

It is obvious that, if perfect results are aimed at, it is just as important that an instantaneous exposure should be as accurate as time exposure, and it is of no use to use an exposure meter, having found by it that the correct exposure is, say, 1-20th, 1-40th, 1-60th, 1-80th, 1-120th of a second, to give (through ignorance of the speeds at which the shutter works) an entirely wrong exposure.

The speed tester consists of a weighted lever, which, when placed on its stand, oscillates on two fine and sharp points and swings seconds. At the upper end of the oscillating lever is a polished nickel-plated convex mirror or button.

A diagram, ruled with white lines on a black ground, is fixed at such a height, and the speed tester so placed, that the bright button (when at rest) is just in front of the round white spot in the centre of the diagram.

The lens of the camera with the shutter to be tested is then pointed towards the speed tester and diagram, which should be sharply focussed on the ground-glass, the camera being placed at such a distance that the image of the diagram nearly fills the ground glass screen of the camera.

The speed tester is then oscillated until the bright button swings the full width of the diagram, and an exposure made with the shutter whose speed it is desired to test.

When the plate is developed and fixed, the negative will show the lines of the diagram, and crossing them at right angles a curved line which represents the path of the oscillating bright spot during the time the shutter remained open. As the distance between each of the vertical lines represents the distance the bright spot moves in the 1-100th of a second, the time of exposure may be readily ascertained by noting the number of vertical it has swung across during the interval of exposure. If more convenient, the test may be made in a room by the light from the burning of a strip of magnesium ribbon.

The "Midget" Sensitised Postcards.—The Rotary Photographic Co. Limited, 14, New Union Street, Moorfields, E.C.

The extraordinary development of the postcard craze has been largely responsible for the impetus given to the production of sensitised cards for making the pictorial postcard at home. The Rotary Co. has been well to the fore in all new developments of the industry. Their latest introduction is the "Midget" postcard (2½ by 3½). They not only supply this new-sized postcard ready to use embellished with portraits of celebrities, but the sensitised cards coated with the well-known "Rotograph" bromide emulsion, with either glossy or matt surface, or the "Rotox" emulsion for gaslight printing are also obtainable at cheap rates, and can be recommended as a full-sized picture can be printed from the quarter-plate negative, and also there are no restrictions with regard to correspondence by inland postage on the address side as with the Panel Book postcard.

graphic Novelties.—W. Tylar, 41, High Street, Aston, Birmingham.

"Perfecta" photographic plate-holder for developing is an ingenious little contrivance of metal and celluloid for gripping the plate during the operation of development, and so saving all risk of plates or stained fingers. No metal whatever is dipped in the developer, but the plate is held and supported by the small celluloid clips, in such a way that there is no possible chance of their slipping at the side when being examined by reflected or transmitted light.

"White Title Ink."—A preparation likely to prove of value for printing in white characters upon the black paper masks or binders for lantern slides; and for greetings on photographs, etc., while other preparations will readily suggest themselves. "Aluminium Bronze Title Ink" can also be employed for similar purposes. "Frames for Miniatures," in black glazed wood pulp and Ormulu gilt. These closely resemble the old ebony and gold frames beloved of our grandmothers, and would prove a very tasteful mount for small carbon portraits. They are intended for oval prints 2½ by 2¼. "Border Negatives for Artists." These embrace a variety of excellent designs made to order on drawings. They are prepared on flat films, and may be printed either side. "The Art of Photographic Dodging." A booklet containing much useful information to the photographer, the price of the various materials and apparatus made or sold by W. Tylar is not the least interesting. "Ferro-Bleach."—A preparation to prove of great use to all who have to deal with blue and white prints by the cyanotype process. The application of this preparation by either brush or pen discharges the blue colour of the print in about a minute. For titling blue prints, for adding to or correcting architects' and engineers' plans, etc., it should be valuable.

Gaslight Printing Frame and Film Developing Dish.—Sold by J. Butcher and Sons, Camera House, Farringdon Avenue, E.C. A new printing frame called "The Mecca," recently put on the market by this firm, strikes us as both novel and useful. It is made for printing by gaslight, and the accompanying illustration explains itself. The back of the frame is immediately heated by means of one spring, and is fitted with handle for holding the burner, or can be stood on any convenient shelf or table. It is 4 in. 4, 5 by 4, and ½-plate, and is comparatively cheap.

"Carbine" film-developing dish is also likely to prove of great use for the user of roll films. It is a well-made porcelain dish, with rounded porcelain bars, the under sides of which are rounded. The film is developed in lengths, and, being drawn regularly through the developer against the bars, it ensures even development.

The dish is spotted at one end, so that developer can easily be poured into the bottle. It takes all sizes of film up to 3½ inches wide, and is inexpensive.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March	Name of Society.	Subject.
18.....	Plymouth Photo. Society	Lantern Slide Making. Mr. W. C. Johns.
19.....	Aberdeen Photographic Assoc.	The Carbon Process. Demonstrated. Mr. W. T. Borthwick.
21.....	South London Photo. Society	To be announced later.
21.....	Camera Club	A Peep at Prehistoric Man. Mr. Cornelius Robbins.
21.....	Ilford and District Photo. Soc.	Wells Cathedral. Mr. J. W. Hodges.
21.....	Bowes Pk. and District Ph. Soc.	The Patinotype Process. Mr. W. H. Smith.
21.....	Glasgow & W. of Scotland P.A.	Control in Development. Mr. Wm. Goodwin.
21.....	Southampton Camera Club.....	Lantern Slide Competition.
22.....	Birmingham Photo. Society	The Making of Lantern Slides. Mr. J. H. Gear.
22.....	Glasgow Southern Photo. Assoc.	Through the Val D'Anzusa. Mr. Tlios. W. Robertson.
23.....	Cricklewood Photo. Society.....	Portraiture by Artificial Light. Demonstrated. Mr. W. Emery.
23.....	Everton Camera Club	Members' Photographic and other Curiosities.
24 to 25.....	Woolwich Photo. Society	Exhibition.
24.....	London & Prov. Photo. Asso.	Some Toning Experiments. Mr. H. C. Itapson.
24.....	Liverpool Amateur Photo. Asso.	The Carbon Process (Single Transfer). Demonstrated. Mr. Robert Bourke.
24.....	Richmond Camera Club.....	Luncheon at an Old Developer. Mr. Oetzmann.
24.....	Hull Photographic Society.....	Alpine Photography. Dr. Hollingsworth. M.R.C.S.
24.....	Watford Camera Club	Competition. Members.

24.....	Gainsboro' Camera Club	Hand Camera Work. Mr. A. H. Hinton.
24.....	Croydon Nat. Hist. and Sc. Soc.	Moscow. Dr. Franklin Parsons, F.G.S.
24.....	Camera Club	Illustrations of Insect Life. Mr. Frederick Enoch.

CAMERA CLUB.

VERY instructive and entertaining, to use an old formula, was the lecture given to the Camera Club last week by Mr. Alfred Hands, who discoursed upon "Lightning, and the Science of Protection Therefrom." The lecture attracted a large audience, as was quite natural, for lightning has a great interest for the photographer, because the camera has provided a means of picturing it in a manner which no painter can ever equal. We can hardly say as much of any other natural phenomenon. It is true that a few artists—including, of course, Turner, who was such a close student of nature—have pictured the true form of lightning, but most of the others have been content with the stereotyped forked appearance, which bears as much resemblance to the real thing as does the scent of violets to the odour of a motor-car. Photography has taught artists that the conventional zig-zag will not do, and although our brethren of the brush are generally rather slow to confess any debt which they may owe to the camera, they cannot deny that in the matter of forms of lightning it is a most reliable guide.

Like many other things, if it can be called a thing, lightning is classed according to the forms it assumes, and meteorologists speak of the sinuous, the ramified, or the meandering type of flash. Mr. Hands showed a number of very fine photographs of these typical forms of lightning. One was especially good, and was taken from a vessel in Sydney Harbour. In this case the columns of fire appeared to be of abnormal size, an effect doubtless due to irradiation. The beauty of the picture was much enhanced by the duplication of the flashes by water reflection.

After showing these pictures of lightning in its various moods, Mr. Hands touched lightly upon that somewhat obscure topic, the origin of atmospheric electricity, and this proved the prelude to a general summary of the theory of thunderstorms. He pointed out that the old belief in the falling of some solid substance from the clouds, "a thunderbolt," was a superstition doubtless brought about by the damage wrought by lightning, which it was found impossible to account for except on the supposition that something solid and heavy had struck the blow.

Although the storms which we experience in this country are neither so frequent nor severe as those which occur in equatorial regions, the damage done by lightning is really very great. Mr. Hands has for the past twenty years collected reports of such accidents as have been caused by lightning, and by means of an enormous map of the British Isles, which was hung for the occasion of the lecture in the club room, it could be seen at a glance where such occurrences

were most common. This was a sketch map, and was dotted all over with tiny coloured wafers, each wafer having a meaning. Thus the black ones denoted fatal accidents by lightning, a red one with a white dot in the centre meant that at that particular place a church had been struck. Other wafers indicated private houses, hay stacks, farm buildings, and so on. Mr. Hands was able to compute the damage from lightning in this country as amounting to between fifty and one hundred thousand pounds annually. Every year about twenty churches are struck, and the same number of persons killed by lightning. Many of the churches might be saved, and so might the lives, if proper precautions had been observed.

A large number of photographs showing damage by lightning formed a most interesting series of pictures. One showed a tree in a park, neither trunk nor limbs exhibiting any trace of damage, but beneath its branches were lying about twenty sheep, the strangeness of their attitudes at once indicating that they were stone dead. The tree had been struck, and the same flash had killed the sheep. There were other pictures of the clothing, all in strips, of labourers who had been struck down in the fields, or whilst seeking protection under a tree. In one of these cases, although the man was entirely stripped by the action of the lightning, he never lost consciousness, and ultimately quite recovered from his terrible experience. And this was not a unique case. Provided that a man's clothing be thoroughly wet with the rain, the electricity runs off the surface to the ground, and he is not seriously hurt.

The importance of providing high or exposed buildings with lightning conductors was illustrated by many photographs of churches and other edifices which had been terribly knocked about. Most of these were not provided with conductors, but others were furnished with rods which proved to be ineffective through the faulty manner in which they were fixed, or the position which they occupied relative to masses of metal in the building itself. Many diagrams showed the good and faulty arrangements as applied to buildings of different designs. A copper rod or tape of sufficient capacity would, if it had a good earth, say a connection with the water-pipes or gas-pipes below ground, effectually protect the building to which it was attached. But if it came near a mass of metal, say at the other side of a wall, there was always the chance of the electricity making for the alternative path, and doing damage on its way. In such a case, the remedy would be to form a small branch metallic connection between the two conducting bodies. On the Continent there have been many cases of ringers being struck in church belfries, for, strange to say, the superstition still exists in certain remote districts that the sound of the bells will frighten away the lightning. Thus the ringers are gathered beneath the bells at the very time when they should keep clear of them. In Yorkshire there is, we are told, among the country boys a less poetical belief concerning the vagaries of lightning. They believe that if the word "lightning" be spoken during a thunderstorm the electricity will, in revenge, tear out the seats of their trousers.

The second part of Mr. Hands' lecture dealt entirely with methods of protection from lightning. The common idea that it is only necessary to stick up an iron rod with one end projecting above the roof and the other buried in the ground is a mischievous one, and a rod so placed will often prove to be a danger rather than a protection. Each building requires to be studied by itself, and the conductor must be placed in such a position that the lightning will not be tempted to choose an alternative path.

Among the most attractive of the pictures shown were several of the work of "steeplejacks" affixing lightning conductors to high chimneys and to church spires, pictures which have been taken at short intervals, so as to show the entire process of raising the ladders from the ground to the parapet. Considering that so much of this dangerous work is in progress, it is a relief to hear that fatal accidents from it only number about three annually. It is interesting to hear that even this profession has been invaded by the other sex. At Bradford there is, or was, a lady steeplejack, who often assisted her husband, and when he was ill carried out his work without hesitation.

The lecture led to an interesting discussion, in which many members joined, and the chairman, Mr. Inwards, called for a very hearty vote of thanks to Mr. Hands for all the trouble he had taken in preparing such an excellent discourse.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MARCH 11TH.—Mr. R. Beckett in the chair. A large meeting, looking forward to Mr. Haddon's paper on "The Action of Light on a Silver Image, Bleached with Mercury Bichloride, and the Elimination of the Mercury Bichloride from the Film," and the meeting enjoyed a paper carefully put together, thoroughly well thought out, and illustrated by experiments. The object of the paper was to show exactly what part the gelatine itself played in the operation of intensification, and Mr. Haddon made all his experiments upon films supplied by Messrs. Wellington and Ward, being of and of very even thickness. The first experiment showed that gelatine film, soaked in a plain solution of mercury bichloride or a solution of mercury bichloride and ammonium chloride gradually assumed a dense opalescence, which no amount of washing would alter; but, if, after a short preliminary washing, a bath of a 1 per cent. solution of either hydrochloric acid or citric acid be given again wash, and repeat the acid bath and washing four or five times it was possible to immerse the film in dilute ammonia, and get it out without darkening of the film.

In the discussion following the paper, Mr. Child Bayley asked Mr. Haddon how the opalescence of the gelatine film was accounted for, which was not so much in evidence in a negative, and also whether the mixture of mercury bichloride with a soluble bromide or chloride was best. Mr. Haddon replied that in the first case a trace of acid was present in the usual formula, and in the other, that he had not yet finished his experiments with films containing silver bromide.

Mr. Somerville, in trying to deposit platinum on a silver bromide image, had tried every acid, organic and mineral, but had not succeeded when the bleaching had been effected in a solution of mercury bichloride acidified with citric acid, if the print after treatment was immersed in hypo it became weaker, but the remaining image was pure platinum. Could Mr. Haddon explain the part that citric acid played, and what is the combination of mercury and platinum?

Mr. Haddon could not decide definitely, but surmised that calomel would probably be formed, and being a reducer the platinum would be deposited.

Mr. Child Bayley had negatives intensified years ago, which were now much denser, i.e., although no apparent visual change had taken place, they took longer to print now than formerly, and asked the reason. Mr. Haddon attributed it to sulphuretted hydrogen in the atmosphere.

Mr. Brown was anxious to know whether hydrochloric acid or citric acid was best. Mr. Haddon recommended citric for addition to the mercury solution, and to soak the plate in after bleaching, and Mr. Child Bayley asked for a definite treatment of negatives based upon the use of acidified mercury bichloride solution. Mr. Haddon replied: Bleach, then wash quarter of an hour, soak in a 1 per cent. solution of acid, wash quarter of an hour, repeat three times, then a final wash.

Mr. Teape had washed a gelatine film (bleached in mercury bichloride solution) for twenty-four hours, soaked in a water containing 6 minims hydrochloric acid to the ounce of water, then washed till no trace of acid remained, repeating the operation till 10 minims of hydrochloric acid were used, and repeating the washing three times until no trace of acid was left. No mercurial deposit upon copper when boiling the gelatine in a test tube could be obtained. This experiment was repeated at the meeting by Mr. Teape, and conclusively proved the extreme difficulty in entirely getting rid of mercury when used with acid.

RICHMOND CAMERA CLUB.

MARCH 10TH.—A lecture on Northamptonshire church architecture was delivered by Mr. F. J. East, of the Kingston Photographic Society. Mr. East had spent a fortnight making a special study of the early English churches in which Northamptonshire abounded, and had taken a large number of photographs of them, with special regard to the architecture. Many of these were shown by lantern, and the points of interest lucidly explained. They comprised a number of views of arches, windows, spires, and towers of different periods, with dogtooth and zigzag ornamentations and other marked peculiarities of the Saxon, Norman, and Early English

es of architecture. Mr. East showed some very fine views of
riors and of old carved pulpits, fonts and tombs, and concluded
some excellent views of Peterborough Cathedral.

SOUTHAMPTON CAMERA CLUB.

CH 9TH.—About 170 members and friends of the above Club,
uding a large number of ladies, responded to the invitation of
Committee, and indulged in a very pleasant conversation. The
eedings of the evening included vocal and instrumental con-
tations of a high order, for which suitable appreciation was shown,
appearance for the first time of the Southampton Camera Club
estra, under the conductorship of Mr. W. H. Trigg, eliciting
h satisfaction. A display of colour photography slides, kindly
by the Lumiere N.A. Company, was much admired, as also were
slides by Mr. F. J. Mortimer, the whole being projected by the
s's limelight lantern, under the management of Mr. G. T. Vivian.
admirable variety of light refreshment was partaken of during
evening, and the whole arrangements were carried out in a highly
satisfactory manner by a special Committee, composed of Messrs.
Copeland, W. R. Kay, F. G. Ryder, T. M. Weaver, and the
secretary, Mr. S. G. Kimber, to all of whom the greatest praise
re, and also to a number of ladies who gave invaluable assistance.
whole proceedings are calculated to give valuable stimulus to the
ody rapidly rising popularity of the Southampton Camera Club.

NEWCASTLE-ON-TYNE AND NORTHERN COUNTIES PHOTOGRAPHIC ASSOCIATION.

A. B. GARDINER, in the course of his remarks during a lecture
the "Development of Exposed Photographic Plates," before the
bers of the above society, laid great stress on the necessity of
ect exposure whenever this is possible; but also showed that
when exposure is not correct, a great deal may be done by
able variations in the developer to produce negatives of good
ity. Under-exposure and over-exposure were dealt with, and
y hints for their correction during development and formulae for
production of suitable negatives for various printing processes
freely given. The after correction of negatives by means of
ction and intensification was also touched upon, as were also the
ssity of careful development, perfect fixation, and thorough
hing. Mr. Gardiner developed several plates exposed under
ring conditions, and obtained good negatives in each case. The
loper recommended for portraiture is pyro-ammonia, while pyro-
is recommended for negatives in which greater contrast is
ired.

WES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.

CH 7TH.—Mr. F. P. Bayne read a paper on birds' nests, etc.,
trated by about 100 lantern slides. In the course of his remarks
became quite evident that the photographing of birds, nests, etc.,
ired an extraordinary amount of determination and patience,
ral instances being mentioned of the expenditure of hours of labour
out result. On one occasion Mr. Bayne spent four and a half hours
tree, standing for the whole of the time on one leg (at a time),
rder to photograph a nest, great difficulty being found to make
exposure owing to the high wind. The slide shown of this nest
Bayne was justly proud of. On another occasion Mr. Bayne
covered a doormouse in a nest, and in his eagerness to obtain a
rd of this made two exposures, only to discover when developing
that they had been made on one plate. Great difficulty was
often found in fixing the camera in position, long exposures being
a necessary owing to the dark and secluded position of some
s. He, where possible, uses a mirror to reflect light on to the
s. Mr. Bayne showed two slides from photographs of Brushers
s, the Hermit of Epping, and told some characteristic stories about
man, who had evidently a very suspicious nature. The members,
ddition to hearing Mr. Bayne, held a competition of photographs
terior, the following members being judged the winners:—1st
2nd, Mr. Bellingham, to photographs of St. Albans Abbey; 3rd,
Craston, a photograph in Enfield Old Church.

HE Koh-i-Noor Pencils.—A delightful illustrated brochure
ing with the merits of these pencils is to hand from the makers,
and C. Hardtmuth. A copy will be gladly forwarded on applica-
to Fredk. E. Potter, 56, Ludgate Hill, London, E.C.

News and Notes.

THE third edition of Julius Verfaesser's standard work on "The
Half Tone Process," recently published by Messrs. Iliffe and Sons,
Limited, differs from the two preceding editions in that it has
been almost entirely re-written and supplied with new blocks. As
a practical guide to the better-known branches of photo-engraving
we see no reason to depart from the favourable opinion of the book
we have so often passed in these pages.

DEATH by Cyanide of Potassium.—Charles Edward Guest, aged 45,
a clerk in Lloyds' Bank, lately residing at Ascot Lodge, Wood Lane,
Shepherd's Bush, poisoned himself at Wormwood Scrubbs on Thurs-
day by means of a preparation of cyanide of potassium used for
photographic purposes. He had been in ill-health for some time,
having suffered from mental trouble, and a coroner's jury at
Hammersmith on Saturday returned a verdict of suicide while tem-
porarily insane.

ROYAL Photographic Society.—At the Technical Meeting on
Tuesday, March 22nd, at 66, Russell Square, at 8 p.m., the following
papers will be read:—"A New Link between Calculating and Effect-
ing Camera Exposures," by Mr. Alfred Watkins; "A New Print
Meter," by Mr. Alfred Watkins. Mr. Arthur C. Banfield will
describe his method of photographing splashes, and show slides and
parts of the apparatus. Mr. F. A. Crallan will show a new tripod
stand.

THE Photographic Society of Ireland announce an exhibition of
photographs to be held in the Leinster Lecture Hall, 35, Molesworth
Street, Dublin, from Monday, 16th, to Saturday, 28th May, 1904.
The judges will be Professor J. Joly, D.Sc., F.R.S.; Alfred Werner,
F.R.P.S.; Reginald Craigie, and additional for lantern slides, H.
Goodwillie and E. Webb-Smith. There are eight classes, and gold,
silver, and bronze medals are offered for competition. A new "open"
class is also announced, viz., for amateurs resident in Ireland, mem-
bers of the society also being eligible for this award. The particulars
and entry forms will be forwarded on application to the Hon. Secre-
tary, Mr. E. Webb-Smith, c/o Royal Dublin Society, Kildare Street,
Dublin.

PLYMOUTH Photographic Society, which will open its exhibition for
six days on May 11th, has again secured as judges Dr. P. H.
Emerson, Mr. Baragwanath King (a West Country artist who has
held successful exhibitions in London), and Mr. F. Shelley (the
director of Plymouth Corporation Art School). The classes will cover
the whole field of pictorial photography, and a silver cup is offered
in the open competitions, besides medals and certificates. The exhibi-
tion will be held in the Athenaeum, which has ample wall space and
a shaded top-light. The Camera Club of the adjoining borough, Devon-
port, follows with its exhibition, and all who desire it may have
their pictures sent on from Plymouth to Devonport. Mr. Wilfred
Grist, 105, Old Town Street, Plymouth, and Mr. A. W. Hicks,
8, Chester Place, are the hon. secs.

MESSRS. TENNANT AND WARD, publishers, of 287, Fourth Avenue,
New York, write: "We believe you to be acquainted with the very
practical value of the researches made a few years ago by Hurter
and Driffeld, concerning the factors controlling exposure and develop-
ment in photography. Papers contributed by Messrs. Hurter and
Driffeld to various learned societies were practically buried in the
journals of these societies soon after their appearance. For some
years there has been a steady demand for their re-publication. To
meet this demand we persuaded Mr. Vero C. Driffeld to embody the
subject matter of these papers in a monograph which has been
published as No. 56 of the "Photo-Miniature" Series. In view of the
value of these researches, we take the liberty of calling your attention
to their publication in monograph form as the Photo-Miniature,
No. 56, entitled "The Hurter and Driffeld System," which can be
obtained from Dawbarn and Ward, Limited, at 6d. per copy.

ROYAL Institution.—The following are the lecture arrangements at
the Royal Institution, after Easter:—Professor L. C. Miall, three
lectures on the "Transformations of Animals"; Mr. L. Fletcher,
three lectures on "Meteorites"; Mr. H. F. Newall, two lectures on the
"Solar Corona"; Professor Dewar, three lectures on "Dissociation";
Dr. A. W. Ward, three lectures on "German Princes and Parties
(1558-1618)"; Mr. H. G. Wells, two lectures on "Literature and the

State"; Mr. Cyril Davenport, three lectures on (1) "Mezzotints," (2) "Cameos," (3) "Jewellery"; Mr. Donald Francis Tovey, three lectures on the "Sonata" (with musical illustrations); and Sir W. Martin Conway, two lectures on "Spitzbergen in the Seventeenth Century." The Friday evening meetings will be resumed on April 15th, when Monsignor the Count de Vava and Luskod will deliver a discourse on "Korea and the Koreans." Succeeding discourses will probably be given by Lieutenant-Colonel David Bruce, the Dean of Westminster, Dr. P. Chalmers Mitchell, Mr. M. H. Spielmann, Professor E. Rutherford, H.S.H. the Prince of Monaco, Professor S. Arrhenius, and other gentlemen.

Patent News.

The following applications for patents were made between February 29th and March 5th, 1904:—

- Film and Plate Holder.—No. 4,908. "Improved photographic film and plate holder and adapter therefor." The Thornton-Pickard Manufacturing Company, Ltd., and Charles Richard Whinfield.
- Colour Photography.—No. 4,941. "Improvements in or relating to colour photography." Adolf Heskkel.
- Daylight-loading Slides.—No. 4,947. "Daylight-loading plate and film slides." Charles H. Shuman.
- Colour Photography.—No. 4,994. "Improved manufacture of coloured photographic images or prints and of sensitive surfaces therefor." Farbwerke vormals Meister, Lucius, and Bruning, Germany. Oliver Imray.
- Printing Frame.—No. 5,143. "Improved photographic printing frame." John Batty.
- Timing Device.—No. 5,188. "Timing devices applicable to photographic development and other appropriate processes." Frederick William Emuss and John William Jones.
- Magazine Change Backs.—No. 5,190. "Improvements in and connected with magazine change backs for photographic cameras." Newton Livingstone Scott.
- Cameras.—No. 5,204. "Improvements in photographic cameras." Jean Frachebourg.
- Flash Lamp.—No. 5,254. "A flash lamp for studio and home portraiture." Tress Azulay.
- Studio Lamp.—No. 5,255. "A studio lamp for studio and home portraiture." Tress Azulay.
- Hand Cameras.—No. 5,327. "Improvements in and relating to photographic hand cameras." Samuel Dunseith McKellen.

Correspondence.

* * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * We do not undertake responsibility for the opinions expressed by our correspondents.

PINACHROME, ETC.

To the Editors.

Gentlemen,—With reference to the articles which appear on pages 202, 207, 208 of your current issue *re* pinachrome, orthochrome, and various other coal tar colours for photographic purposes, manufactured by Messrs. Meister, Lucius and Bruning, it may not be generally known that we are the sole agents for that firm in this country, and we shall be pleased to supply full particulars to intending users, and to send price lists on application.—Yours truly,

17, Philpot Lane, London, E.C.,
March 11th, 1904.

STRIPPING OLD NEGATIVES.

To the Editors.

Gentlemen,—I have received the "Almanack" for 1904, for which many thanks. I notice amongst the articles two methods of cleaning the film from old negatives, both of which are a matter of days. I have been in the habit of using a method which I consider much simpler. Take any old negative and immerse it in water for about

half a minute or a minute, take it out of the water and wipe with towel, you can then roll the film away from the glass easily, starting from a corner of the negative. If the negative has been aluminized it is all the easier. I send you this method as it does not seem to be generally known.—Yours faithfully,

PERCY M. CLARKE

Victoria Falls, Livingstone, N.W. Rhodesia,
February 10th, 1904.

INTERNAL REFLECTIONS IN THE CAMERA.

To the Editors.

Gentlemen,—Mr. A. Lockett raises some interesting questions in his letter, but he has rather missed the point of mine. I did intend to suggest that orange paper would be a perfect remedy for reflections in all cases, but only that it would most probably be better than so-called "dead black," which, in many cases, has the appearance of a bad polish. If the paper is better than the black with a slow emulsion I don't quite see why it should not also be better with a fast one, leaving the matter of orthochromatic plates out of the question.

A fast ordinary plate may be slightly sensitive to orange light, but the conditions in the camera are very different to those which existed in the case I mentioned. In that, the reflections were caused by magnesium burning for a minute or more in close proximity to the reflecting surface, and they were sharply focussed on the sensitive surface. In the camera the reflections are scattered and much less powerful, while exposure is very short if a rapid plate is in use. These conditions may more or less counteract the extra sensitivity of the plate, which is certainly not "rapid" as regards orange light. Even with orthochromatic plates little action is produced by orange light unless the exposure is longer than the usual duration of a snapshot. With time exposure on an orthochromatic plate no doubt dead black would be better than orange paper, which might be altogether ineffectual if a filter screen was used. In any case should think orange paper to be undesirable in a stand camera, a light interior is anything but advantageous for visual focussing. In suggesting the trial of orange paper in the camera the idea of the camera alone was in my mind.

I am uncertain from Mr. Lockett's letter whether he speaks from experience in approving the use of orange paper with slow ordinary plates; but if he does some particulars of his experience would be interesting. As regards its actual use in cameras I am only suggesting possibilities.

With regard to the hood screen, a circular hood is better than a rectangular one, and is more easily fitted than a rectangular one, but the latter, if properly adjusted, must surely give more efficient protection to a rectangular plate.—Yours, etc.,

C. WELBORNE PIPER.

March 11th, 1904.

THE METRIC SYSTEM.

To the Editors.

Gentlemen,—Your correspondent Mr. Welborne Piper in his letter of the 5th inst. rightly says that your pages are not a place to give lessons in elementary arithmetic, but he proceeds to argue against the metric system, and in favour of a duodecimal system of weights and measures in a manner which is only suited to a school. The argument is inapplicable to our system of weights and measures because, even if a duodecimal system were demonstrably preferable, it in fact nowhere exists, certainly not in the British islands.

What is certain is that those who are most familiar with computation in all the forms in which it is applied are unanimously in favour of the decimal system of multiplication and division of the units. It is not denied that for certain purposes and for certain sorts of problems vulgar fractions, especially the simpler ones are more convenient, but then no reasonable advocate of the metric system ever proposed to prohibit the use of such fractions when preferred. It is easy to see that by selecting problems we may make it appear that one method or other of the various modes of dealing with them is comparatively easy, and it is not at all easy to put into a small space a selection of such problems as would give an absolutely fair comparison, and is still less easy to avoid partiality in selecting a few. The safest plan then surely is to appeal to the judgment of experts of wide experience and their evidence is practically unanimous.

There is an old story of a learned gentleman who wanted a written

made in France, which among other qualities should be thirty times as high, and he found that he could only express this to the cent by using many decimals; he had, however, a table which varied the conditions, and a friend brought the carpenter who made the necessary dimensions with his metric rule and found no difficulty in completing the job. That is a specimen of the difficulties to be found in the metric system, when difficulties are expected they are to be found, and when they are boldly faced with a desire to overcome them they vanish.

Of course it is not supposed that a certain amount of inconvenience will not be found at first in adopting the new system, and this will especially occur with the less educated classes and those whose arithmetical operations have run in a groove, but all experience in other countries shows that it does not take long to overcome this, and that once overcome no one wishes to revert to the old confusion. In the last paragraph but one of his letter I fear that Mr. Piper presumed on the ignorance of your readers; the problem involves possession of accurate weights, or of weights whose errors have not been determined, and which have been extraordinarily carefully prepared, and of such balances as are rarely available. Then the errors in the weights are variable with the density of the atmosphere, and that matter so too is the weight of the chemical and of the water. Accurate determinations of all these things would take a considerable time, and in fact no man in his senses would approach the problem in this manner. The practical solution is quite easy, and the fact that a cube centimeter of water is not always a kilogram in weight, and the liter exactly 1,000 cube centimeters would not affect the solution. The metric system is in practice found to be as perfect as paper, and it is used by all who have accurate work to do in large quantities. It seems safe to say that in some form an Act to make the metric system compulsory will before long pass the legislature, and it would surely be better for the skilled to use their knowledge to make things easy for the unskilled, rather than to spend time and talents in fostering prejudice.

I have spoken of the metric system and decimal weights and measures as practically the same for no other decimal system has been proposed which has the faintest chance of reception. Moreover, notwithstanding the want of perfect agreement between the units theoretically defined, and the accepted representatives of them in use (and is likely to be) no other in which the advantages resulting from the inter-dependence of the various units is so great.—I am, gentlemen, yours faithfully,
J. F. TENNANT.
March 14th, 1904.

THE DECIMAL AND METRIC SYSTEMS.

To the Editors.

Gentlemen,—It is very evident from Mr. Welborne Piper's letter that he is not conversant with metric measurement and calculation, though he sets himself up as a judge of a system he persistently insists on mixing with other systems of calculation, and finds out to his satisfaction that he cannot do so to advantage. I know perfectly well that there is nothing new in the so-called Duodecimal system, which Mr. Piper has the coolness as bringing forward against the metric system, or at all events the Decimal system. I have challenged Mr. Piper to show that the so-called Duodecimal system is able to take the place of the Decimal system as a system of notation and as a fundamental principle out of which a harmonious system of weights and measures may be evolved. The answer is not forthcoming, but instead of it haggling over side-issues, setting as examples chosen as it may be. But I will give the answer myself:—The Duodecimal system is a device for working certain calculations with a certain amount of facility. It is not a system capable of forming the basis of a better system than the Metric unless the present notation be changed from a Decimal to a Duodecimal one.

I agree that decimals may be an abomination to one who wants to keep the two systems and prefers "thirds, sixths, eighths, and sevenths." I have deliberately stated, a half-hearted adoption of the Decimal system is no good, and must be aggravating to one so prejudiced as your correspondent. To one versed in the Decimal system and its practical application, the Metric system, the thirds, sixths, and sevenths are an abomination. That is where we differ. We are told, further, that decimals cannot be used alone, "for when we do so, "we cannot reach a high state of efficiency," and any monetary and metrical system which knows decimals only "is essentially defective." Almost all

monetary systems of civilised nations, our own excepted, are based on decimal subdivision. Has any one ever heard from experience that their systems were "essentially defective?" It is clear to Mr. Piper that I must be all wrong; for example, the litre of water does not weigh 1,000 grams, but 997.8066! Why the four decimals when they could have been expressed in vulgar fractions in fewer figures, more clearly and with greater precision. I should like to see them so expressed. Now, the conditions under which a litre weighs 1,000 grams are known of water to every one conversant with the Metric system. They are water at its greatest density—viz., 4°C. (appr. 39°F.) under normal barometrical pressure. The 997.8066 are thrown down without stating under what conditions they are supposed to be correct. The same argument would, however, hold good for the ounces of water or any other Imperial measure the weights of which would vary with its volume exactly in the same way. As a taskmaster Mr. Piper is highly amusing. I have done many similar calculations to the one he sets me to do, both in the un-Decimal and the Decimal measurements, and have invariably found the latter the simpler and more precise of the two.

I am finally made to say that I consider our present crown to be worth 96 half-pennies. I can hardly conceive a schoolboy to misread my meaning in this manner when suggesting a decimal division of our monetary values. It is hardly worth pen and ink to argue that I did not do so, nor do I see any good in continuing this discussion unless a fair attempt is made to argue the question of the best system of weights and measures with real facts instead of mere assertions.—I am, yours truly,

215, Shaftesbury Avenue, London, W.C.

March 14th, 1904.

J. R. GÖTZ.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

J. W. Tattersall, 15, Avenue Parade, Accrington. Photograph, Snow Scene, Oak Hill Park, Accrington.
T. Bacon, 24, Royds Street, C.-on-M., Manchester. Photograph of House, Crowcroft Park, Manchester.

PYRO.—Sorry we can add no further information at present. We will bear your question in mind when details are available.

"SALARY."—Such work may be characterised as of the fourth rate professional order. It should entitle you to a salary of £0s. a week, and would be absolutely useless in South Africa.

J. DOLMAN.—Such an emulsion would not be sufficiently sensitive for your purpose. Better consult Abney's "Photography with Emulsions."

FESTINA LENTE.—Messrs. Marion and Co., of Soho Square, London, publish a book on the subject, to which we refer you. We cannot at present afford space for the details you require.

J. ROBERTS.—Review of the book you mention has not yet appeared in our columns, but will be dealt with in due course. You do not give your address in your communication.

"AN OLD SUBSCRIBER."—To make sure that the pictures are out of copyright, we should recommend you to make a search at Stationers' Hall. Consult the Copyright Act, printed in each edition of the ALMANAC.

E. CROSS.—Messrs. Marion and Co. would probably be able to supply you with the plush frames bearing photographic views. As

to the negatives, no doubt, if you advertised them in the JOURNAL, giving an idea of the subjects, you would find purchasers. There is a very great demand for good negatives just now.

E. R. BROOKS.—We do not see what you can do in the matter. The negative has been accidentally broken, and it is usually understood in the trade that printers are not responsible for the breakage of negatives. To recover damages you would have to prove wilful damage. We do not reply to queries by post. The prints have been returned as desired.

SILVER ON NEGATIVE.—"TROUBLED" asks: "Would you be kind enough to let me know how to remove nitrate of silver from negative?" In reply: We presume you mean silver stains from damp paper? If so, they may often be removed by rubbing them over with an alcoholic solution of iodine until they disappear. Then refix in a new solution of hyposulphite of soda. The iodine solution should be about the colour of dark sherry.

ADDRESS WANTED.—G. V. SIMMONS writes: "Kindly let me know where I can get the 'Photographisches Wochenblatt,' for this month, which gives particulars of new incandescent lamp referred to in 'B. J.' for March 11th?" In reply: We refer our correspondent to the BRITISH JOURNAL ALMANAC, which publishes every year a list of the principal foreign photographic periodical literature, and the addressed of the publishing offices.

COPYRIGHT.—E.H. writes: "About ten years ago I photographed a well-known athlete, for which he paid me at the usual rates. He is now, I believe, in Canada, and I find that a certain athletic journal has reproduced (in England) two of the photos. Can I claim damages? The photos were not registered or made copyright in any way. Should not they have written to me and paid for reproducing them?" In reply: Claim damages? Certainly not. You were paid for your work. What more do you want or expect?

LENSES.—"SANDFORD ORCAS" writes: "Will you please say which of the two following lenses you would choose for a half-plate camera for landscape work and large heads—(1) A rapid landscape lens (single), 7 x 5, stops F. 8 to F. 64, price 25s.; (2) a Suter landscape lens, No. 3, fitted with wheel diaphragm, price 32s.? I do not know the focus of either, but should like to know, probably are equal." In reply: As the lens is required for large heads, as well as for landscapes, we should recommend the one that has the largest focus, and the largest working aperture.

BROMIDE PRINTING.—H. J. BLISS AND Co. ask: "How to best fit up a small room for bromide printing; is electric or gas light best? Water to be laid on; no daylight available: or advise where we can find the necessary details." In reply: We do not know where you will find any published details, as we think none are required beyond what would suggest themselves to those who are going to work in the room. You will require a sink suitable for the size work you propose to do, and also dishes, a dark-room lamp, and a light for the exposures, either electric, incandescent, or gas will answer. If the latter be employed, we should recommend the incandescent.

COPYRIGHT.—BORDERER writes: "Some time ago we had private theatricals, and employed a country photographer to take some groups and single figures. The proofs were sent round to the different actors so that they might order those they preferred. Three or four dozen were ordered. The photographer sent in a bill for the proofs at the rate of 3s. each for whole, 2s. each for cabinet, and 1s. 6d. each for single figures. What I want to know is—(1) Is he entitled to charge for the proofs when copies have been taken? (2) If he is, am I entitled to the negatives?" In reply: Unless there was a contract on your part to pay the photographer, he is entitled to make such charges, and the negatives are his property.

B. T. H. writes: "Enclosed please find six rough prints taken with the intention of obtaining exhibition pictures. I want you to criticise same as such, and through the medium of your valuable journal let me know which you consider will make the

worthiest exhibit when enlarged? Should space permit, I would also like to know (1) does the moon in No. 1 add to the general effect or otherwise; (2) is the belt of trees made in No. 2 too pronounced for the making of that picture; what size and colour would you suggest for enlargements of the chosen picture?" In reply: (1) Four, five, and six are good photographs, and might be used. The moon does improve. No. 2. Yes; much too pronounced. (3) About by 12. A sepia would perhaps be the best for the subjects.

STUDIO QUERY.—E. M. BOSS asks: "Will you kindly advise me the following questions? I have a small studio 12 x 7, which I am going to remove. I intend enlarging it to 12 ft. wide and adding a piece 13 ft. on to it, making it 25 ft. long; also intend having the light on the single slant system. I want to ask you if it would be effective in a studio that size or would you advise side and top light? There would be about 9 x 8 ft. of light in the single slant, and a north-east light." Reply: The studio, as shown in the sketch, would be a very good one, but if the single slant be adopted, should advise that the glass be brought a little lower, say, foot nearer the floor. It is quite a matter of opinion as to whether the single slant or a top and side light is best. Both are good.

LACK OF EMPLOYMENT.—"SEEKER" writes: "I am desirous of obtaining a situation as copyist, but find it difficult to get a class of work I want. I have made a study of isochromes, work, copying painting, etc., both with dry plates and collodion emulsion, and should like a situation to do same, London. I have tried advertising in the JOURNAL, but with no effect. What other course would you recommend? What salary do you think one might reasonably ask, having twenty years' experience and a wide knowledge of carbon, platinum (S. and B.) and the silver printing processes?" In reply: We can only suggest your advertising for the employment you desire. We are afraid there are a large number of assistants out of employment at the present time. As regards salary, we can say nothing, as so much depends upon individual ability.

PHOTOGRAPHY AS A PROFESSION.—J. W. BURRELL says: "Having an idea of taking up photography as a profession, I have applied to a local artist, and he requires a premium of £20 for a twelve months' tuition, covering everything. Is £20 above the usual figure asked? He also says I will be able to easily earn from £2 to £3 per week as operator-retoucher at the end of the twelve months. Will there be any difficulty in doing so thoroughly proficient, and any chance of that figure being increased? Would you advise me to 'go in' for it professionally, as I have heard of its being 'cut up' very much in the provinces?" In reply: We should advise you to hesitate before entering photography for a livelihood, seeing that the photographic labour market is already so over-stocked with assistants. We think you would be unusually fortunate if you succeed in obtaining an engagement at a salary of from two to three pounds a week, with only twelve months' experience in a small country place. We think you might probably spend your £20 to better advantage in some other way.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Radium everywhere. The interest in this mysterious body is kept up by all kinds of unexpected news; we recollect no fact of pure science that has held the public mind and held it so long as has radium. We have described the disappointed expectations of the inhabitants of Bath in the finding that, though radium was discovered in the waters of that famous resort, it was not there in payable quantities. Now we learn from the Geneva Archives of Sciences that air and soil are radio-active. Experiments were made to find the effect was inherent in the air. It was proved not to be the case; the soil conveyed the activity. Some specially rich soil was tested, and found to contain a trace of radium, and it was concluded that the radio-activity of the atmosphere in its vicinity was derived from it, as the activity decayed at the same rate as that induced by known radium salts. Then again at the Cambridge Philosophical Society, Professor Thomson described the results of an examination of a large number of samples of water from different parts of the Kingdom. In nearly every case the radio-active gas which is present in Cambridge tap water, and is probably identical with the emanation from radium, was present. In order to find its source, a number of clays, gravels, and sands were examined—still radium! It was also in garden soil from the laboratory garden, in the Cambridge gault, in gravel from a pit at Chesterton, in still greater quantities from the sand on the sea-shore at Whitby, in the blue lias at Whitby, in powdered glass, one specimen of flour! This is very wonderful. What does rise to some little anxiety is the probability that the

presence of radium may be offered as an excuse for bad plates and bad workmanship. Who shall say?

* * *

Blondlot's n-Rays.

This most recent addition to what we may term radiation records continues to be matter of controversy, if not even of actual doubt. In *Nature*, a week ago, Mr. W. A. Douglas Rudge writes: "In trying to repeat Blondlot's experiments I have met with the usual lack of success," but in the preceding week the same journal had a letter from so well-known a worker in Röntgen-ray work as Mr. A. A. Campbell Swinton, who states that "It is by no means difficult to repeat some of the effects M. Blondlot describes; but, so far as my observations go, these effects when obtained are in every case due to heat." Mr. Swinton refers, further, to some experiments, whose results were communicated to the French Academy, to the effect that the luminosity of calcium sulphide screens is increased when they are placed in a weak magnetic field. He says that: "Having spent considerable time in endeavouring to confirm this observation without the slightest success, it would interest me to know whether anyone else had tried it, and with what success." After all that the various effects described are really objective and not subjective scarcely seems to admit of doubt when we read the long array of names of writers of papers sent to the Academy of Sciences quite recently. Thus, in one séance, we have M. Blondlot himself detailing further experiments, M. Bichot giving the transparency to n-rays of various metals, and also showing that liquids under pressure emit the rays, M. Crénien describing the magnetic rotation and their plane of polarisation; M. Bayard on the same subject; MM. Dubois and Charpentier treating of the action of the rays on the senses; and so on. So far the work done seems mainly with the luminous screen: if a screen can be made luminous it should be able to reproduce itself on a photographic plate, and there can be little doubt, if such permanent records could be produced and shown, they would have a tendency to put down the scoffers.

* * *

Irradiation Effects.

At a recent meeting of the Royal Microscopical Society a discussion took place upon the cause of certain effects that produce an imperfect mental image of microscopic objects under the conditions described, and an explanation was given, which form the brief précis of the report before us appears to be at the least superfluous. Most photographers who have done any photomicrographic work have tried their hand at a blow-fly's tongue, and are familiar with the minute spinous hairs that are shown with a good photograph from a good specimen. When one of these hairs is seen by the eye through the microscope, first on a dark and then on a light ground, a considerable difference in size was dis-

cernible, and the difference was explained as being due to "anti" points, and a table was given showing the amount to be added to the micrometric measurement of the bright ground image. Mr. Gordon, who originated the anti-point theory, had made accurate drawings of both bright and dark ground images, and found a ratio of 45 to 65 between them. The photographic point of this discussion lies in an acquaintance with the effect of pinholes in a negative. In the days of wet-plate work pinholes were a very common defect, but are nowadays less frequently met with; but every expert worker used to be familiar with a remarkable quality of these defects. A conspicuous hole in the negative did not show in the print, and the puzzle to be solved was, why did they not show? The explanation then given was not "anti-points," but irradiation. It was known that when a bright object was cut into by a dark object the light portion appeared larger than its true size warranted, while the dark portion was smaller. The effect was markedly discussed years ago at the time of the transit of Venus across the sun. When the planet was almost but not quite apparently touching the sun, a "drop" or "ligament" shot out and joined the two. This was explained as being due to irradiation just described, which was physiologically accounted for as being due to the rods and cones of the retina immediately contiguous to those receiving the image in eye being excited sympathetically, and so causing the brain to receive a larger image than the true retinal image. Returning now to the pinhole negative, the matter works out in this way. When the plate is looked through at a bright light the pinhole, when on a dark ground, appears through irradiation larger than it really is, and, further, when it is printed upon paper, its reduced true size is represented, which again is subject to irradiation, the surrounding white appearing to encroach upon the minute speck of black, and so reducing it again to the eye. The moral to be derived from this is that when small transparent spots appear in a negative they should not be spotted out until a trial print shows that they really need it. It is to the inexperienced really surprising what a number of good-sized pinholes may be visible in the negative and yet disregarded. It is a difficult matter to dexterously spot out a minute hole, and it must be remembered that a white spot on a darker ground, such as would be produced by over-spotting a pinhole, will, by virtue of this same irradiation, appear to the eye larger than it really is.

* * *

Miniature Painting.

Some persons are inclined to regard photography as a kind of devouring monster which makes it its business to intrude into every branch of art and take the bread out of the mouths of talented and deserving men. And they quote the case of the wood engravers who, before the advent of the process-block, ruled the roost so far as illustrated journalism was concerned. Or possibly they instance the case of the steel engraver, who has been altogether abandoned now that such beautiful results are obtainable from photogravure. At one time a cry went up that the daguerreotype had killed miniature painting, and for a number of years it seemed that that was the case. Owing, however, to the labours of a few enthusiasts this beautiful method of portraiture has not been allowed altogether to sink into oblivion, and although we, editorially, have the interests of photography at heart, we are unfeignedly glad to see that it has not, as was at one time expected, driven the art of painting on ivory out of the field. For there is a charm about these pictures which is seldom seen in the photograph, and it would be quite a disaster if the art of producing them was lost. It is difficult for the imagination to recall the time when the photograph was not and the miniature reigned

supreme; when every gallant would carry on his snuff-box on the top of his malacca cane, or attached to some other indispensable part of his gay equipage a tiny portrait of the loved one of his heart; and when ladies would follow suit with corresponding portraits of their beaux on rouge box or brooch. Some of the older photographers among us can remember how, in the early days of sun pictures, the custom of using portraits as personal adornments was common. It was, of course, reflected from the earlier days of miniature painting. As we have already indicated, the miniature received what many believed to be its death-blow at the hands of Daguerre, but there were a few men who seemed determined that the art which began about the time of Holbein, and was brought to such vigorous perfection by Cosway and others, should not be allowed to die without a struggle. A handful of miniatures were generally to be found on inquiry each year at the exhibition of the Royal Academy, but it was not until 1896 that the revival of the art began to be talked about. At this time Mr. Alfred Praga founded the Society of Miniaturists, and gathered round him a band of young artists who were determined that the cabinet photograph should not have it quite its own way, and that the little picture on ivory should have once more a chance of recognition. And their efforts have been crowned with success. We may be quite certain that many of these little pictures are copied from photographs, as must certainly be the case in painting the miniature of one who has joined the majority. So that we may say that in this revival of an almost forgotten art the photographer is not altogether out of it. The miniature has much to recommend it, apart from its beauty. It is as permanent as any form of painting that we know of; indeed, it might be said that, considering the nature of the material upon which the colour is laid, it must be more permanent than either an ordinary oil or water-colour work. It is not costly, and the pictures, being of small size, take up little room. It is the fashion now for people to live in snug apartments and in flats, and the wall space available is at a premium. Miniatures, alternated with the more sober-garbed photograph, are regarded as the best kind of mural decoration for such homes.

* * *

Electric Illumination.

Electricity has now been in common use as a light-giver for so many years that it may be profitable to inquire whether we are getting the best possible results from the means at our disposal. The little glow lamps used for interior illumination and for exterior display leave little to be desired, for they give an effective light and can be used in situations in which the open flames of lamps or gas jets would be quite inadmissible. They can also be employed to follow the lines of ornamental ceilings and other architectural adornments as no other form of illuminant can be. They are not cheap to maintain, but the extra price paid for their employment is counterbalanced by their safety, their cleanliness, and their decided convenience. Arc lamps are mostly in request for street lighting or for the illumination of large halls, and when we come to consider the general way in which they are installed we have some reason to think that we do not benefit as much as we might by the initial light given out by the white-hot carbons. The common custom is to enclose each arc light in a glass globe, which is hung from a standard some thirty feet above the roadway. It is to the nature of this globe, or lantern, that we wish to direct attention, for there is no doubt at all that, in the majority of cases, a good 50 per cent. of the light is lost before it finds its way to *terra firma*. The other night, in a suburban street, we happened to come across one of these lamps, the globe of which had been broken. There was a jagged piece of glass, a few inches in area, broken out from

lower part. From this orifice a splash of most brilliant light struck the pavement, and the contrast between this brightly lighted-up patch and the diffused light around was as great, or seemed to be as great, as the difference between daylight and moonlight. Hence we think that we are justified in putting the loss of light in these particular ground-glass globes at quite 50 per cent. In other cases, where lanterns with "chipped glass" panes are employed, the loss is probably not so great, but it seems to us that there is a distinct need of some medium better than either of these kinds of glass which will diffuse the light and at the same time not impoverish it to the extent described. Ground glass has another disadvantage in very quickly glowing under the action of light. Anyone who has had occasion to replace a gas globe, part of which is ground, will have noticed how the old globes suffer by comparison with the new ones; they have darkened with a darkness which no washing will remove. It may be considered necessary to take off the glare of the electric arc light by the use of some kind of translucent medium, but we doubt if this is the case with lamps placed far above the level of the eye. At any rate, it seems to be bad economy to furnish a brilliant light at considerable cost and then to shut out its radiance in the way described. We may mention that at the Geological Museum at Jermyn-street electric arc lights are employed in a very satisfactory, and we have quite a unique, manner for interior illumination. The naked arc is furnished with an inverted reflector, so that the light is not seen, but is cast up on to the ceiling. From this white surface a diffused light comparable to that of daylight is shed all over the hall with excellent effect. It is difficult at first to see where the light comes from, for there are no tell-tale shadows to tell one of its origin. It would be worth while for our municipal authorities to do something of this kind for street illumination. The reflecting surface might take the form of an inverted cone of porcelain, or some other material of a like kind, which would at the same time protect the naked carbons from the

* * *

Photography and the Solution of Problems.

It is not so many years ago that the use of sulphite of soda in photographic operations was entirely unknown, and when Berkeley first introduced it, the numerous repetitions of its claims were needed before photographers would even look upon it; years passed before full recognition of its value was given. At the present time it is scarcely a dark-room from which it is absent or elopement performed without its aid. Metabisulphite has its place in many workers' hands, and especially in the dry-plate maker's formulae, although the cases are few in which every purpose is not subserved by the use of the ordinary sulphite of soda, to which a certain amount of potassium has been added, a plan which, moreover, helps towards uniformity, for metabisulphite in crystal is less stable than sulphite, and the same may be said of their respective solutions. A matter not to be lost sight of in times when economy has to be the order of the day is that the former is much dearer than the latter, either weight for weight or in the quantity required to produce a given preparative action. But, superior as the neutral salt is in its preserving properties, some little care is required in keeping crystals and much care as regards the solution. For crystals it will suffice to see that the bottle containing them is always kept well corked: we have seen samples of crystals scarcely touched with efflorescence taken from a bottle in daily use for upwards of a year. The cask, however, was one of a kind which deserves more frequent adoption than hitherto has been the case; in fact, we have only seen it in use, though one extensive manufacturer at

Bow usually sends out his goods packed in these casks. They are virtually air-tight, and are provided with a lid which fits accurately and as tightly as a cork in a bottle. We heartily commend them to our readers' notice. When sulphite is kept in stock solution particular care should be taken to see that the stopper of the bottle (it should never be kept in a corked bottle) is an accurately-fitting one and always kept in its place, and replaced as quickly as possible whenever the bottle is used. Otherwise the solution is very liable to absorb oxygen from the air, and by consequent conversion of its sulphite into sulphate to become quickly inert. Touching this conversion, some singular facts with regard to dilute solutions have recently been published in a well-known German scientific paper. When the water used for dissolving the salt in weak solution was distilled from a boiler with a silver or tinned copper, still some 200 minutes were required for oxidation (from the oxygen dissolved in the water) of half the salt present; when the purest water possible to obtain was used, as much as from 1,500 to 1,800 minutes had to elapse; while when water distilled by the aid of an iron still head, and so containing traces of iron, was made use of, the change was half completed in from ten to twenty minutes. The velocity of oxidation is extraordinarily sensitive to traces of copper, and it is stated that a marked acceleration of the oxidation is produced by a solution of sulphate of copper of a thousand-millionth normal strength, or by merely dipping a piece of bright metallic copper in the water for less than a minute. Other substances had an opposite effect; thus mannitol in a hundred-thousandth normal strength delays the oxidation by 50 per cent., and the salts act in the same manner still more powerfully—one two hundred and fifty thousandth normal reduced the speed of oxidation 25 per cent. These facts are so remarkable that they produce a tendency to speculate whether or no some photographic reactions in which sulphite takes part may not be influenced to some extent in an analogous manner.

* * *

Photographed Ghosts.

We remember reading, some years ago, a story by the author of "Vice Versâ," the scene of which was laid in Ghost-land, and in which was described a meeting of spirits to discuss the question whether or not such a thing as a human being actually existed. It was a clever piece of topsy-turveydom, for the problem of the disembodied spirit is as old as the hills, and has for centuries been the subject of argumentation among the descendants of Adam. Certain it is, too, that there are many who seriously believe that the records of ghosts having been seen do not point to any hallucination of the brain on the part of the observers, but to a semi-transparent actuality, which is the intangible form which the more spiritual part of our nature takes to itself after the death of the body. It has been claimed by many, as our readers know, that these ghostly visitors, who seem to appear to only a very few persons, who are known as mediums, will, under certain vague conditions, permit themselves to be photographed. But among the great majority of photographers these pictures have been generally regarded as frauds. They labour under one disadvantage in common, in that it would be extremely easy for any photographer, if he were so minded, to produce the same effects. In other words, we have never yet seen one which could not be easily faked. And we have just been carefully examining a collection of many dozens of these pictures, which were thrown open to public exhibition on Friday and Saturday evenings last by the Spiritualist Society of Chiswick. When works of any kind are thus exhibited in public they must run the gauntlet of criticism, and their exhibitor, Mr. H. Blackwell, will doubtless be

prepared for adverse comments. Our attention was first called to this unique show by a notice in the *Daily Chronicle*, and from that publication we are able to glean a few curious particulars concerning these pictures, which the paper referred to calls "weird" and "uncanny," "interesting and marvellous." The same authority quotes Mr. Blackwell as saying that "only one photographer in England was able to take the portraits, and he has now retired from business." But our readers will naturally ask, "What are the pictures like in this extraordinary one-man-show?" Well, there is a family likeness between them all. There is generally only one sitter, and this, we presume, is Mr. Blackwell. But over his shoulder, or in some other part of the picture, is seen the shadowy outline of someone else, and generally this someone else is a person of some note. To again quote from the *Daily Chronicle*, "Mr. A. Blackwell has placed on view a large number of spirit photographs, the 'sittings' for which, in his own words, have been given to him in fulfilment of promises made by the disembodied, whose materialised forms peep over Mr. Blackwell's shoulder." We attach a good deal of importance to this statement as to promises fulfilled, as will presently be seen. But we may first note that the ghosts presented include Browning, Tennyson, Longfellow, Charles Dickens, Huxley, Darwin, Napoleon, Rev. Haweis, John Knox, and sundry other notables. Some of these, we have no hesitation in saying, are taken from pictures, and in nearly every case the face of the ghost is framed in stiff new muslin. This gives the conventional translucent outline to the spirit form. Mr. Blackwell, we are told, indignantly repudiates any suggestion that the results are obtained from what is known as a "double exposure." We have no wish at all to impugn his veracity. But we are by no means so sure of the *bonâ fides* of the unnamed photographer. Here it is that, we think, the significance of the *promised* sittings comes in. What we mean is this. Suppose that a photographer, intent upon fooling a credulous mortal, were to arrange with a medium in collusion with him that the spirit of Shakespeare should appear on a promised occasion. Would not this postponement of the appearance give time for preparation of a model for the ghost and its partial exposure on the plate to be subsequently used for the portrait? The pictures did not attract us either by their pictorial merit or their technical excellence. We have seen plenty like them before, although there is apparently only one man gifted enough to produce them.

"The Cinderella of the Arts" was the title of a lecture on photography recently given at Staines by Mr. Thomas Bedding, F.R.P.S., Editor of THE BRITISH JOURNAL OF PHOTOGRAPHY.

BOROUGH Polytechnic Photographic Society.—Mr. P. C. Cornford has been obliged to resign the secretaryship owing to increased business responsibilities. The news was received with much regret by the society. Pending a fresh appointment, all communications should be addressed to the acting secretary.

THE Royal Photographic Society's Practical Demonstrations.—The fourth of the series of practical demonstrations on printing processes will be held at 66, Russell Square, on Tuesday, March 29th, at 8 p.m., the subject being "Carbon Printing," by Mr. John H. Gear. The following is the synopsis:—(1) Reasons for the selection of the process; (2) the making of the paper or tissue; (3) manufactured tissue sensitive and insensitive; (4) home sensitising and its latitude; (5) single transfer prints upon paper and opal; (6) double transfer prints upon paper, opal and ivory; (7) the negative; (8) printing the necessary precautions, exposure, mounting and developing, local development and reduction, fixing and washing; (9) spotting and working upon the print. Mr. J. Fielder Haden will occupy the chair.

MISCONCEPTIONS AS TO PHOTOGRAPHIC COPYRIGHT.

It seems more than passing strange, seeing that so much has appeared in the pages of the JOURNAL on copyright law, and that the Act itself is printed annually in the ALMA MATER, that there is still so much misconception amongst photographers as to their rights—and supposed rights—when regard to copyright. That such do exist is evidenced by the number of queries that are constantly being replied through the "Answers" column. The existing Copyright Act, it is pretty well known, was passed in 1862, and is clearly explicit, and gives photographers all the protection that they can reasonably desire if they choose to avail themselves of it; but too often they neglect to do so, and then find their work pirated by others, so that they have no redress. That is their fault, and not that of the Act. In not a few instances photographers imagine that they possess rights to which they are in no way entitled, and not infrequently complain of the present state of copyright law. As just stated, the present Act is a reasonable one, and cannot well be improved upon so far as the interests of photographers are concerned. There certainly would not be in that direction by any of the different Bills that have from time to time been promoted to amend the present Act if they had become law.

Here is a very common grievance amongst professional photographers, though it is quite an imaginary one. He takes, say, a portrait in the ordinary course of business, and afterwards sees the picture reproduced in a magazine or, maybe, a newspaper. Or, perhaps, he may find that the sitter, who may only have paid for a single portrait, upon which much time was expended in the expectation of future orders, has placed the picture in the hands of another photographer to be enlarged, or, possibly, to be reproduced in cheap form. This is certainly annoying, but, after all, there is little really to complain of. The photographer has been paid his charge—whether much or little—for his work, and the copyright belongs to the sitter. In these circumstances it would be absurd if the customer could not do as he likes with his own property, be it a photograph or anything else.

There is an idea prevailing with some that if a picture does not bear the imprint "Copyright," there is no copyright in it. This is a fallacy, for it is not at all necessary that the picture should be so marked. On the other hand, it is illegal to mark a photograph copyright in which there is no copyright, as it implies a legal right that does not exist. We may mention en passant, however, that we are not aware of proceedings being taken against anyone for this illegality, so far as the word copyright is concerned. In the case of the illegal use of the word "patent," where no patent had been granted, although Provisional Protection had been obtained there has been more than one conviction, and substantial penalties and costs inflicted.

It is sometimes thought that there is no copyright in a photograph until after it has been registered. That is a mistaken idea. Copyright exists immediately the picture is taken, and is the property of someone. No proceedings, however, can be taken until it has been registered by its owner, and registration may be done at any time. But it must be understood that the owner cannot recover penalties or damages for anything done before the registration was effected. The Act is very clear on this point. Although there is no remedy for anything done before registration, there was no offence in law committed, action can, however, be taken for anything done afterwards. Section 6 of the Act makes it an offence to sell, publish, exhibit, let for hire, or offer for sale, etc., any copyright work. Therefore anyone whose pictures may have been pirated before the copyright in them was registered, may still register it and

restrain further sale, as the sale or exhibition will then be illegal. He can then obtain an injunction and recover damages, but not penalties, as he would have been able to had the registration been effected before the piracy was committed. This fact may not be so well known as might be to some who have had their photographs reproduced as picture postcards and the like without their consent. They can, after registration, by injunction, restrain the sale of the piracies and recover damages. The latter would doubtless not be large, but the sale would be stopped. We may add that it is not necessary that proceedings be taken against those who actually made the reproductions, as they may be taken against all and everyone selling them or offering them for sale. This some may be glad to know, as it may enable them to obtain some compensation for the injury done them. For example, many Stationers and others who hold a large stock of picture postcards of local views, etc., made without the permission of the one who took them, and who had neglected to register them, would often be glad to make terms with the photographer after he has registered the copyright, either by way of a royalty or otherwise, rather than risk being mulct in damages and the costs of an injunction, and also having to sacrifice his stock of pictures.

Some imagine that if a sitter, whose portrait has been taken for, gives the photographer verbal permission to register the copyright in it, that, after the registration, he has a legal copyright in it. That is a mistaken idea. The photographer must formally assign the copyright to him in writing, and the assignment should bear a sixpenny agreement stamp. Then the copyright will be legally his, even if he has been paid for taking the portrait. Some persons when they purchase a business, together with the stock of negatives, amongst which may be some copyright ones, imagine that the copyright passes to them. It does not, however, and he cannot proceed against anyone pirating them unless the copyrights have been separately assigned to him, and the assignments duly registered at Stationers' Hall. If a sitter has his portrait taken in the ordinary course of business and does not pay for it, some imagine that they are entitled to register the copyright in it, and prevent the photographer making use of the picture for any purpose of his own. That, however, is not so. In the case of *Boucas v. Cooke* it was decided that as the sitter had had the portrait taken in the ordinary course, and in that way had incurred a debt that could be sued for, the copyright was not vested in the photographer. In the above we have pointed out one of the misconceptions that some photographers labour under with regard to copyright; but there are others, though, perhaps, of somewhat minor importance, but space will not allow of them being dealt with now.

JOTTINGS.

SUPPOSE it may be taken as a delicate compliment to THE BRITISH JOURNAL OF PHOTOGRAPHY that Liverpool this week is the opening of the Northern Photographic Exhibition, which from all accounts will include a very fine selection of up-to-date photographic work. It is fifty years since THE BRITISH JOURNAL OF PHOTOGRAPHY was founded in that very town, and it is fitting that at the end of the half-century its birthplace of the B.J. should witness the best possible modern manifestations of the art which the paper was founded to encourage and foster. Those readers of this year's JOURNAL who have followed with intelligent interest the extracts from the 1854 volume which have recently been given in these pages will hardly need reminding that one of them, indeed the very first, dealt with an exhibition of the Liverpool Photographic Society in 1854, for which premiums on the best specimens of the art were offered. So does history repeat itself. In congratulating the Liverpool photographers on the step they have taken, and wishing their exhibition the very highest artistic and popular success, I will append

the hope that if the New Zealander should arrive here half-a-century hence, he will find the Liverpool Society holding an exhibition of photographs, and THE BRITISH JOURNAL OF PHOTOGRAPHY recording the fact.

It must be about sixteen years since the late Mr. Traill Taylor, subsequent to a visit which he paid to Liverpool, printed in these pages an article dealing with what Liverpool had done for photography. Taylor, whose historical knowledge on his subject was probably unequalled at the time, and has not been excelled since, save perhaps by one contemporary journalist whose name will occur to many of my readers, rendered the very highest tribute to the early photographic workers of the great city on the Mersey. The collodion emulsion process which forms the basis of modern gelatine photography was originated at Liverpool by Sayce and Bolton. At one time, too, Liverpool was the English emporium of Transatlantic productions once so popular amongst professional workers. I need hardly say that I allude to the celebrated house of John J. Atkinson. Such renowned amateur workers as the late Canon Beechey and Mr. Osmund Green were in the long-ago connected with Liverpool, as was Mr. Peter Mawdsley, a pioneer worker in gelatine and collodion dry plates. It is permissible to conjecture that had Liverpool not taken the prominent part which it undoubtedly did in perfecting photographic technique, such an exhibition as that which is being opened to the public, as these pages are making their way through the post, would not have been found feasible. We to-day are profiting by the labours of the unrewarded experimentalists of the past.

So far as British photography is concerned, it may be truthfully said that Liverpool at the present time holds the one living English link between the photography of 1904 and the photography of fifty years ago. If I am wrong here I trust that some older photographer will take the opportunity of correcting me. I do not think I am. Some weeks ago a letter appeared in these pages from a member of the present Liverpool Society, stating, although he had reached the patriarchal age of ninety-odd years, Mr. James Alexander Forrest was still in the land of the living and taking an interest in photography. Mr. Forrest was one of the editors of the "Liverpool Photographic Journal" fifty years ago, and anybody who cares to turn up the first volume of that journal may see for himself what a strong and vivid interest in photography Mr. Forrest then took. In the directly personal sense the news that Mr. Forrest still retains a direct interest in matters photographic came to me as a most agreeable surprise. I was turning over, the other evening, some of the many photographic scraps which I take the greatest pride in preserving—I mean those having some associations of a particular or individual character; such scraps, indeed, as most of us, whether we be photographers or not, take care to preserve. I came across a 12 by 10 group taken by Mr. J. B. B. Wellington in the ruins of St. Mary's Abbey, York, in the year 1896. In that group, besides the humble writer of these lines, and one or two others, there were the owners of three great names identified with photography in Liverpool—H. P. Robinson, Paul Lange, and James Alexander Forrest. Robinson and Lange have, alas! gone over to the majority. This was on the occasion when Robinson was president of the Convention at Leeds. The meeting that year gave great impetus to photography in the Yorkshire city.

Paul Lange's death is so recent as to hardly need detailed reference here. Suffice it to say that in his time he was a pillar of the Liverpool Association, the most genial of men, and one of the best producers of photographic lantern slides in Britain. When I come to write the autobiography to which I made reference at a recent London festival I think I shall devote a portion of a chapter to the adventure which the editor of a contemporary and myself had with poor Lange at the Shrewsbury Convention of 1895. He quite failed to see the point of a small joke that was played upon him, in respect of which he differed from his fellow victim, Robinson, who submitted with the utmost meekness to initiation into a photographic association which no longer exists. Robinson had family connections in Liverpool. I spoke just now about the York group in which so many able Liverpool photographers

figured. It was on that occasion that I had the very great pleasure of meeting and shaking hands with the veteran Forrest, and I shall never forget the kindness and cordiality with which—old man that he was and probably better versed in the practice and history of photography than anybody else present on that occasion—he came forward, gave me an almost paternal greeting, and spoke of the honour he felt in meeting me. The honour, of course, was on my side. I do not know whether Mr. Forrest will be present during the exhibition which is to be held in Liverpool during the next few days. If he is, I am quite sure he will receive a cordial and respectful welcome from all those who meet him; at any rate, I trust I may be pardoned if, while recalling the association of this JOURNAL with Liverpool, I indulge in these few reminiscenary details. With regard to Sayce and Bolton, I never met the former, but as to poor "W. B.," my recollections are alike of the pleasantest and the saddest. It was my melancholy duty some years ago to see that he was tenderly laid to rest in a little Hertfordshire churchyard. Is it too much to hope that one of these days his memory will be perpetuated in some permanent form?

There will be other opportunities of telling in greater detail the part which Liverpool has played in the history of photography, so that I may leave the subject at present; but as I take it the exhibition partakes of the international character which we have been wont to associate with the displays held in such great photographic centres as Bristol, Leeds, Newcastle, Dundee, Glasgow, and elsewhere, it may not be an unfitting occasion to ventilate a small grievance with regard to what should be a much greater display of British pictorial photographic work, namely, that at the International Exposition at St. Louis. From what one gathers, if British pictorial photography is worthily, or, at any rate, adequately represented across the Atlantic this month it will be nothing short of miraculous. No official systematic attempt seems to have been made to secure a thoroughly representative display of photographs from leading British workers. The duty of collecting the exhibit appears to have been handed over to two or three gentlemen of a particular school, whose names, though commanding respect in virtue of personal probity and ability, will hardly command general approval on the score of breadth of view and catholicity of taste. There have been one or two protests already uttered in the matter, and it is as well that the subject should be further ventilated until some satisfactory explanation of the transaction is made public. Not being an exhibitor I have no axe to grind in the matter, but in common with many other photographers who have the best interests of British photography at heart, I should like to know by what process the appointment of those having charge of British pictorial photography at the St. Louis Exhibition was arrived at, how these gentlemen made their selection, and the nature of their credentials. Like Rosa Dartle, I am asking for information, and I pause for a reply. Meanwhile, will my friend, Mr. J. C. Strauss, note that so far as I can discover no British photographic institution has had anything whatsoever to do with the organisation of the pictorial photographic exhibit for St. Louis, and that therefore whatever is shown cannot by any possibility be considered as either representative, typical, or impartially selected?

One or two correspondents have recently submitted specimens of their portrait work, and have asked opinions on the same. From the replies given it would appear that the work resembles those crude abominations of the Mile End Road, which satisfy the æsthetic aspirations of those charming specimens of femininity, the factory girls, to whom a right rev. prelate referred in such sympathetic terms the other day. By the way, I wonder if his Lordship has ever mixed with the class on a Bank Holiday afternoon at, say, Hampstead Heath? An opportunity for the professional rightly struggling to produce good portrait work, and not knowing where to look for direct guidance and incentive, has been offered him by the authorities of the Royal Photographic Society this week at 66, Russell Square, where a display by three masters—William Crooke, Frederick Hollyer, and T. C. Turner—is on view. The exhibition, which will probably be re-enforced by examples from the studio of that charming Bohemian, Mr. Furley Lewis, deserves to be visited by every portrait photographer, and as non-members are invited to view it no doubt the hall porter at Russell Square will be kept very busy during the next few weeks. During the last day or two I have been turning over a somewhat

large collection of portraits of myself, and I have an idea that when the society is hard up for subject matter for an exhibition a one-man show of a distinctly novel kind might be organised; that is to say, a display of photographs of individual taken by different photographers at different periods of his life, or even contemporaneously. I have about a dozen different photographs of myself. The points of resemblance between any two of them are so few that doubts are often cast upon their being portraits of the one original. If this illustrates the old saying that point of view is everything, it also, to my mind, shows that the personal element in portrait photography is much greater than is supposed.

My friend, Mr. W. A. Rouch, who is, I believe, the surviving member of his historical house, sends me a copy of a letter which he received from a correspondent on the subject of the keeping qualities of Rouch's plates. This is what he says: "Yesterday I was particularly anxious to photograph a view and having no roll-film, and only a hand camera fitted for film I had to 'make shift.' I had a small stock of quarter plates which had been lying on one side for years, and with a little stamp paper I fixed one in the camera; it was 3.30, and I was very doubtful as to exposure on account of the age of the plate so I used F. 11, and gave 1-25th sec., and on another plate used F. 16, and gave one second exposure. I tried to develop one of the plates (I don't know which) with ferrous-oxalate, but found it apparently under exposed. I then tried the other with hydrokinone, and got a most excellent negative, full of detail, and without the very slightest sign of fog or stain, or anything detrimental. All this may sound very ordinary until you know the date of the plates, and then I think it becomes a little short and marvellous. I bought the plates in 1889 from Mr. Owen Angier who was a photographer in this city (Exeter), but has since relinquished business, and he had marked the box July, 1888. The plates were 'Rouch's Extra Rapid Gelatine Plates.'" This excellent testimony to the keeping qualities of English-made plates, and probably establishes a record. If any of our readers have had similar experiences I shall be glad to hear of them. I myself have used plates quite as old, or nearly as old, with satisfactory results, but such an experience is probably not very common, as few of us keep unused plates so long.

One or two notes with regard to society matters may fitly conclude this somewhat lengthy batch of jottings. The publication of the arrangements for the Derby Convention suggests the reflection that the picnic character of this agreeable annual gathering has received the sign manual of official recognition, as for the first time no mention is made of papers to be read in the evenings. As a lover of photographic picnics I make no complaint of this omission, but it is open to question whether the longevity of the Convention is assured by the entire elimination of the solid fare from the annual menu. A word as to the P.P.A., whose annual dinner was held last week. As one who had something to do with the formation of this association I am pleased to be the recipient of a commemorative medal, which passes into my collection of heirlooms. The membership of the association does not increase so rapidly as might be desired. On the other hand 10 per cent. of the professional photographers in the United Kingdom seems a very reasonable proportion. I was reading the other day about a professional organisation conducted on similar lines, and the proportion seemed to be about the same to the total number of the profession. One plank in the platform of the P.P.A. is probably destined to form, in the future, its greatest element of strength, namely, examinations for assistants. If a suitable scheme for this purpose can be devised and carried into effect a great benefit will be conferred on professional photographers. At the present time there is a great dearth of really capable assistants, men of artistic instincts, good studio knowledge, and technical ability, and as the assistants of the present are to be the masters of the morrow it stands to reason that unless something be done in this matter the future outlook for professional photographers is not of the brightest. Thanks not only of professional photographers but of the community in general will be due to the P.P.A. if they could ensure by practical examination the presence in our midst of a body of refined and capable photographic studio assistants; for, as we once observed, your studio photographer is brought into an intimate relation with his sitter as a doctor is with his patient so that personal fitness and good studio manners are just as much essentials to success in studio photography as the necessary personal and scientific qualifications are in medical and surgical practices.

SOME SPECTROSCOPIC NOTES ON TRICHROMATIC PHOTOGRAPHY.

II.

For confirmatory tests Dr. Eder constructed a chart of vermilion, chrome yellow, emerald green, ultramarine, and ethyl violet, with small patches of the normal trichromatic printing inks underneath, a dead black border, and a scale of greys, the latter being somewhat similar to an H. and D. strip. The black border and the white paper represent the deepest blacks and highest white of the original, whilst the grey scale presents the half tones. He gives the spectrum reflected from these colours, but whereas this chart cannot be reproduced, the only spectra which interest us specially are those of the normal printing inks, chrome yellow, milori blue, and alizarine red lake. In these the letters above refer to the Fraunhofer lines and the titles are given underneath. It is, of course, unnecessary to point out that the white paper represents the colours reflected by these pigments.

As to the particular method of determining these spectra it is somewhat beyond the scope of this digest, but due regard has been taken of the reflection of white light.

Fig. 1.—Chrome yellow.

Chrome yellow has good covering power, and the absorption spectrum may be estimated through a very thin film by transmitted light. The absorption in the red is little; it reflects the red fairly well, but orange, yellow, and yellow-green up to E-F. is very good. In the green λ 542 the reflection is weaker, still weaker from λ 500-480; blue-violet and ultra-violet are strongly absorbed.

Fig. 2.—Alizarine red lake.

Alizarine red-lake has a good transparency for the red, the absorption band begins at λ 602, with a maximum at λ 592-500, sinking at the latter point. It is tolerably translucent to the blue from λ 486, still more to λ 470, and thence into the blue-violet and ultra-violet.

Fig. 3.—Milori blue.

Milori blue, which is a particular shade of Berlin blue, absorbs the whole of the red and orange; with thin films it is transparent to bright green; thicker films absorb the whole of the spectrum to the blue, as shown by the dotted line.

Painted and printed colours always reflect colour mixtures, and it is besides their own particular colour zones of the neighbouring colours in the spectrum; for instance, chrome yellow not only reflects pure spectrum yellow, but also orange and green. Green pigments reflect yellow and bright blue, and frequently also a narrow zone in the extreme red. Most violet pigments reflect not only blue, but also considerable quantities of bright red.

This peculiar property of paints and printing inks increases to a great degree the possibility of separating their photo-

graphic action by suitable light-filters and colour sensitive plates, and explains on the other hand the practical experience that three-colour filters which leave gaps in the spectrum allow all pigments in a painting to act more or less.

For the yellow printing plate the negative should be produced by the blue-violet rays, and the green rays should act as little as the yellow and red. Wet collodion, bromo-iodide collodion emulsion, gelatino-bromide, and gelatino-chloride of silver plates, the chief sensitiveness of which lies in the blue and violet, may be used.

The wet collodion plate, with acid iron development, gives with normal exposure the violet and blue to λ 437, and even with over-exposure does not extend further towards the bright blue or blue-green. As practical work proves that excellent yellow printing plates may be thus made, it was found that a normal negative from λ 437 to the end of the violet is satisfactory, but an inclusion of the ultra-violet gave rise to trouble in trichromatic work.

Gelatino-chloride of silver, with chemical development, in spite of its dominant violet sensitiveness, is unsuitable for trichromatic work, as it is not sensitive enough to bright blue, though with over-exposure this fault may be overcome, but the general sensitiveness is too little for it to be of any value.

Pure silver iodide collodion is also not sensitive enough, and bromo-iodide is much to be preferred, as it is more sensitive to bright blue and more sensitive to blue violet.

Gelatino-bromide of silver, with generous exposure, is very sensitive to violet and up to bright blue, and also slightly into the blue-green, and with very long exposures the action extends into the yellow beyond the D line. Practice has proved that the blue-green in pigments acts too strongly on gelatino-bromide plates, and the interposition of a violet filter is advisable. Ammonio-oxide of copper filters give less satisfactory results.
